17.330.1 Detailed Description

Mathematical graph edge between two GraphNode endpoints.
GraphEdge is not a GenESyS process Connection and does not imply Entity flow. It supports directed or undirected interpretation, optional numeric weight, self-loops and parallel edges. A GraphNetwork decides whether the edge is interpreted as directed or undirected when the edge is inserted.

17.330.2 Member Function Documentation

17.330.2.1 _check()

```
bool GraphEdge::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.330.2.2 _loadInstance()

```
bool GraphEdge::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.330.2.3 _saveInstance()

```
void GraphEdge::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.

17.330.2.4 show()

```
std::string GraphEdge::show ( )  [override], [virtual]
```

Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

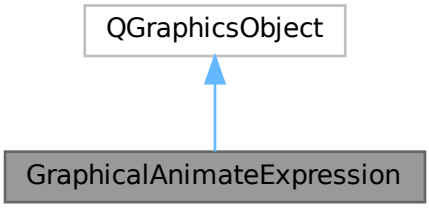
Human-readable summary used by traces and debug output.

Reimplemented from ModelDataDefinition.
The documentation for this class was generated from the following files:

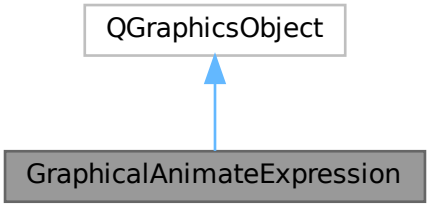
- plugins/data/ModalModel/GraphEdge.h
- plugins/components/ModalModel/GraphEdge.cpp

17.331 GraphicalAnimateExpression Class Reference

Inheritance diagram for GraphicalAnimateExpression:



Collaboration diagram for GraphicalAnimateExpression:



The documentation for this class was generated from the following files:

- applications/gui/genesys/graphicals/GraphicalAnimateExpression.h
- applications/gui/genesys/graphicals/GraphicalAnimateExpression.cpp

17.332 GraphicalAssociation Class Reference

The documentation for this class was generated from the following files:

- applications/gui/genesys/graphicals/GraphicalAssociation.cpp

17.333 GraphicalAutomaticPositioningStrategy Class Reference

Public Member Functions

- virtual ~GraphicalAutomaticPositioningStrategy ()=default

  Strategy interface for automatic placement of graphical data definitions.
- virtual QPointF **initialComponentLayoutOrigin** () const =0

  Returns the origin used when laying out the first graphical component.
- virtual QPointF dataDefinitionPosition (const QRectF &anchorBounds, const QSizeF &childSize, int index, int count, bool upperArc, int radialLayer) const =0

  Computes the position of one child item around an anchor rectangle.

17.333.1 Constructor & Destructor Documentation

17.333.1.1 ~GraphicalAutomaticPositioningStrategy()

```
virtual GraphicalAutomaticPositioningStrategy::~GraphicalAutomaticPositioningStrategy ( )
[virtual], [default]
```

Strategy interface for automatic placement of graphical data definitions.
Implementations decide how child graphical items are laid out around an anchor item. The GUI uses this abstraction so layout policy can be selected from preferences without changing the reconstruction code that consumes the strategy.

17.333.2 Member Function Documentation

17.333.2.1 dataDefinitionPosition()

```
virtual QPointF GraphicalAutomaticPositioningStrategy::dataDefinitionPosition (
            const QRectF & anchorBounds,
            const QSizeF & childSize,
            int index,
            int count,
            bool upperArc,
            int radialLayer ) const  [pure virtual]
```

Computes the position of one child item around an anchor rectangle.

Parameters

anchorBounds	Bounds of the item being decorated.
childSize	Size of the child item to place.
index	Zero-based child index in the current arc.
count	Number of children to place in the same arc.
upperArc	True when the child should be positioned above the anchor.
radialLayer	Additional radial layer for nested attachments.

Returns

Scene position where the child should be placed.

The documentation for this class was generated from the following file:

- applications/gui/genesys/services/GraphicalAutomaticPositioningStrategy.h

17.334 GraphicalAutomaticPositioningStrategyFactory Class Reference

Factory for the automatic positioning strategy selected from GUI preferences.
`#include <applications/gui/genesys/services/GraphicalAutomaticPositioning↩ Strategy.h>`

Static Public Member Functions

- static std::unique_ptr< GraphicalAutomaticPositioningStrategy > **createFromPreferences** ()

  Creates the preferred automatic positioning strategy instance.

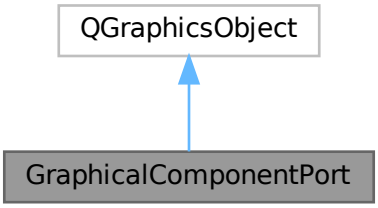
17.334.1 Detailed Description

Factory for the automatic positioning strategy selected from GUI preferences.
The documentation for this class was generated from the following files:

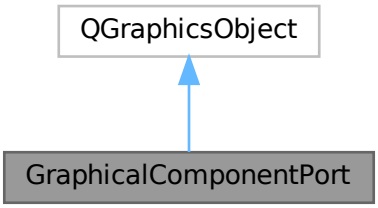
- applications/gui/genesys/services/GraphicalAutomaticPositioningStrategy.h
- applications/gui/genesys/services/GraphicalAutomaticPositioningStrategy.cpp

17.335 GraphicalComponentPort Class Reference

Inheritance diagram for GraphicalComponentPort:



Collaboration diagram for GraphicalComponentPort:



Public Member Functions

- GraphicalComponentPort (GraphicalModelComponent ∗componentGraph, bool isInputPort, unsigned int portNum=0, QGraphicsItem ∗parent=nullptr)

  Visual port attached to a graphical component for connection routing.
- QRectF **boundingRect** () const override

  Returns the local bounding rectangle used for hit testing and painting.
- void **paint** (QPainter ∗painter, const QStyleOptionGraphicsItem ∗option, QWidget ∗widget) override

  Paints the port handle using the component and selection styling.
- qreal **width** () const

  Returns the logical width used by the port geometry.
- qreal **height** () const

  Returns the logical height used by the port geometry.
- void **addGraphicalConnection** (GraphicalConnection ∗connection)

  Registers one connection attached to this port.
- void **removeGraphicalConnection** (GraphicalConnection ∗connection)

  Unregisters one connection attached to this port.
- unsigned int **portNum** () const

  Returns the port number within the owning component.
- bool **isInputPort** () const

Returns true when this is an input port.

- GraphicalModelComponent * **graphicalComponent** () const

  Returns the owning graphical component.

- QList< GraphicalConnection * > * **getConnections** () const

  Returns the list of connections currently attached to this port.

Protected Member Functions

- virtual QVariant **itemChange** (QGraphicsItem::GraphicsItemChange change, const QVariant &value) override

  Keeps the port aligned when its parent component moves or is reparented.

17.335.1 Constructor & Destructor Documentation

17.335.1.1 GraphicalComponentPort()

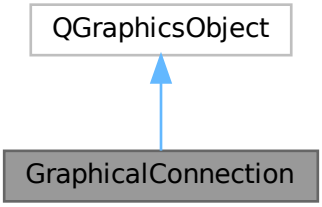
```
GraphicalComponentPort::GraphicalComponentPort (
            GraphicalModelComponent * componentGraph,
            bool isInputPort,
            unsigned int portNum = 0,
            QGraphicsItem * parent = nullptr )
```

Visual port attached to a graphical component for connection routing.
Ports are the connection endpoints used by the scene to attach `GraphicalConnection` items to a component. The port item keeps track of connected edges and exposes enough geometry for the scene to render and route links consistently.
The documentation for this class was generated from the following files:

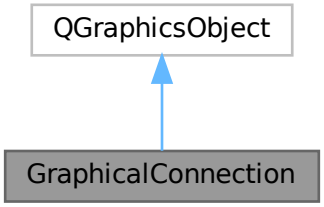
- applications/gui/genesys/graphicals/GraphicalComponentPort.h
- applications/gui/genesys/graphicals/GraphicalComponentPort.cpp

17.336 GraphicalConnection Class Reference

Graphical edge that represents model-level component connections.
`#include <applications/gui/genesys/graphicals/GraphicalConnection.h>`
Inheritance diagram for GraphicalConnection:



Collaboration diagram for GraphicalConnection:



Public Types

- enum class **ConnectionType** : int { **HORIZONTAL** = 1 , **VERTICAL** = 2 , **DIRECT** = 3 , **USERDEFINED** = 4 }

Public Member Functions

- GraphicalConnection (GraphicalComponentPort ∗sourceGraphicalPort, GraphicalComponentPort ∗destination↩ GraphicalPort, unsigned int portSourceConnection=0, unsigned int portDestinationConnection=0, QColor color=Qt::black, QGraphicsItem ∗parent=nullptr)

  Creates a graphical connection between source and destination ports.
- **GraphicalConnection** (const GraphicalConnection &orig)

  Copy constructor used by restoration and clipboard flows.
- virtual ∼**GraphicalConnection** ()

  Releases the connection item and its auxiliary routing state.
- QRectF boundingRect () const override

  Returns item bounding rectangle for Qt painting system.
- QPainterPath **shape** () const override

  Returns the precise clickable shape around the visible connection path.
- void paint (QPainter ∗painter, const QStyleOptionGraphicsItem ∗option, QWidget ∗widget) override

  Paints connection path and selection handles.
- Connection ∗ **getSource** () const

  Returns auxiliary source Connection metadata.
- Connection ∗ **getDestination** () const

  Returns auxiliary destination Connection metadata.
- GraphicalComponentPort ∗ **getSourceGraphicalPort** ()

  Returns source graphical port.
- GraphicalComponentPort ∗ **getDestinationGraphicalPort** ()

  Returns destination graphical port.
- GraphicalModelComponent ∗ **getSourceGraphicalComponent** () const

  Returns source graphical component resolved from source port when available.
- GraphicalModelComponent ∗ **getDestinationGraphicalComponent** () const

  Returns destination graphical component resolved from destination port when available.
- void updateDimensionsAndPosition ()

  Recomputes local geometry based on current port positions.
- GraphicalConnection::ConnectionType **connectionType** () const

  Returns configured connection routing type.
- unsigned int **getPortSourceConnection** () const

Returns source output port index associated with model connection.

- unsigned int **getPortDestinationConnection** () const

  Returns destination input port index associated with model connection.

- void **setConnectionType** (GraphicalConnection::ConnectionType newConnectionType)

  Sets routing type used during painting.

- QList< QPointF > **getPoints** () const

  Returns sampled scene points used for serialization/inspection.

- bool **usesCurvedStyle** () const

  Returns true when the current visual style uses curved model connection paths.

- QPainterPath **animationPathForImage** (qreal imageWidth, qreal imageHeight) const

  Returns the scene path followed by entity animation in modern connection style.

Protected Member Functions

- virtual bool **sceneEvent** (QEvent *event) override

17.336.1 Detailed Description

Graphical edge that represents model-level component connections.
`GraphicalConnection` links two `GraphicalComponentPort` objects and keeps auxiliary `Connection` metadata synchronized with the simulator model.
The item is also used for the diagram-level routing that the GUI derives from the model structure when rendering connections inside the scene.

Todo Evaluate decoupling model metadata from this item to keep this class purely visual.

17.336.2 Constructor & Destructor Documentation

17.336.2.1 GraphicalConnection()

```
GraphicalConnection::GraphicalConnection (
            GraphicalComponentPort * sourceGraphicalPort,
            GraphicalComponentPort * destinationGraphicalPort,
            unsigned int portSourceConnection = 0,
            unsigned int portDestinationConnection = 0,
            QColor color = Qt::black,
            QGraphicsItem * parent = nullptr )
```

Creates a graphical connection between source and destination ports.
Bloco 1: inicialização de metadados de conexão. Mantemos wrappers de Connection para facilitar sincronização com kernel.
Bloco 2: configuração visual/interativa do item.
Bloco 3: cálculo inicial de geometria da conexão.
Bloco 4: registro bidirecional nas portas para atualização quando houver movimento.

Todo Extrair para método dedicado `_bindPorts()` para legibilidade.

17.336.3 Member Function Documentation

17.336.3.1 boundingRect()

```
QRectF GraphicalConnection::boundingRect ( ) const  [override]
```

Returns item bounding rectangle for Qt painting system.
Bloco 1: calcula margem extra baseada na porta para reduzir clipping visual.
Bloco 2: retorna retângulo local com margem.

17.336.3.2 paint()

```
void GraphicalConnection::paint (
            QPainter * painter,
            const QStyleOptionGraphicsItem * option,
            QWidget * widget )  [override]
```

Paints connection path and selection handles.
Bloco 2: normaliza coordenadas locais considerando orientação relativa.
Bloco 3: gera path de desenho com base no tipo de roteamento.
Bloco 4: renderiza o path final da conexão.
Bloco 5: desenha “handles” quando selecionado.

17.336.3.3 updateDimensionsAndPosition()

```
void GraphicalConnection::updateDimensionsAndPosition ( )
```

Recomputes local geometry based on current port positions.
Bloco 1: coleta de geometria absoluta de portas.
Bloco 2: projeta esta conexão para um sistema de coordenadas local mínimo.
Bloco 3: mantém apenas atualização geométrica local.
The documentation for this class was generated from the following files:

- applications/gui/genesys/graphicals/GraphicalConnection.h
- applications/gui/genesys/graphicals/GraphicalConnection.cpp

17.337 GraphicalConnectionStyle Class Reference

Public Types

- enum class **RouteType** { **Horizontal** , **Vertical** , **Direct** , **UserDefined** }

Static Public Member Functions

- static bool **usesModernCurves** ()
- static QPainterPath **modelConnectionPath** (const QPointF &source, const QPointF &destination, RouteType routeType, bool modernCurves)
- static QPainterPath **diagramConnectionPath** (const QPointF &source, const QPointF &destination, bool modernCurves)
- static QPointF **pointAtProgress** (const QPainterPath &path, qreal progress)

The documentation for this class was generated from the following files:

- applications/gui/genesys/graphicals/GraphicalConnectionStyle.h
- applications/gui/genesys/graphicals/GraphicalConnectionStyle.cpp

17.338 GraphicalContextMenuController Class Reference

Builds context menus for the graphical model view using existing main-window actions.
`#include <applications/gui/genesys/controllers/GraphicalContextMenuController.h>`

Public Member Functions

- **GraphicalContextMenuController** (ModelGraphicsView *graphicsView, Ui::MainWindow *ui, QAction *openSubmodelAction, std::function< ModelGraphicsScene *()> currentScene, std::function< void()> actualizeActions)

  Creates the controller without taking ownership of UI or scene objects.
- void **handleGraphicsViewContextMenu** (QContextMenuEvent *event)

  Shows the context menu matching the item or background under the mouse.

17.338.1 Detailed Description

Builds context menus for the graphical model view using existing main-window actions.
The controller intentionally reuses QAction instances from the main window so shortcuts, enabled state, icons, checked state, and command handlers remain centralized.
The documentation for this class was generated from the following files:

- applications/gui/genesys/controllers/GraphicalContextMenuController.h
- applications/gui/genesys/controllers/GraphicalContextMenuController.cpp

17.339 GraphicalDataDefinitionLayout Class Reference

Pure helper that computes arc placement for graphical data definitions.
`#include <applications/gui/genesys/services/GraphicalDataDefinitionLayout.h>`

Static Public Member Functions

- static QPointF arcPosition (const QRectF &anchorBounds, const QSizeF &childSize, int index, int count, bool upperArc, int radialLayer=0)

  Computes a child position along the upper or lower arc around an anchor item.

17.339.1 Detailed Description

Pure helper that computes arc placement for graphical data definitions.
This helper keeps the geometry math independent from the GUI controllers and scene code so layout policies can be reused in both live rebuilds and persisted-state restoration.

17.339.2 Member Function Documentation

17.339.2.1 arcPosition()

```
QPointF GraphicalDataDefinitionLayout::arcPosition (
            const QRectF & anchorBounds,
            const QSizeF & childSize,
            int index,
            int count,
            bool upperArc,
            int radialLayer = 0 )  [static]
```

Computes a child position along the upper or lower arc around an anchor item.

Parameters

anchorBounds	Bounds of the anchor graphical item.
childSize	Size of the child item to place.
index	Zero-based child index.
count	Total number of children in the arc.
upperArc	True for the upper arc, false for the lower arc.
radialLayer	Additional radial offset used for nested attachment rings.

Returns

Scene position for the requested child.

The documentation for this class was generated from the following files:

- applications/gui/genesys/services/GraphicalDataDefinitionLayout.h
- applications/gui/genesys/services/GraphicalDataDefinitionLayout.cpp

- applications/gui/genesys/graphicals/GraphicalImageAnimation.cpp

17.342 GraphicalModelBuilder Class Reference

Service that reconstructs graphical components/connections from kernel model data.

`#include <applications/gui/genesys/services/GraphicalModelBuilder.h>`

Public Member Functions

- GraphicalModelBuilder (Simulator ∗simulator, ModelGraphicsView ∗graphicsView, ModelGraphicsScene ∗scene, std::map< std::string, QColor > ∗pluginCategoryColor, QTextEdit ∗console)

  Creates the reconstruction service used by load/rebuild compatibility flows.
- void setModelLevelFilter (unsigned int modelLevel)

  Restricts this builder and the target scene to one ModelDataDefinition level.
- void **clearModelLevelFilter** ()

  Clears the level restriction and restores full-model rebuild semantics.
- void recursivalyGenerateGraphicalModelFromModel (ModelComponent ∗component, List< ModelComponent ∗ > ∗visited, std::map< ModelComponent ∗, GraphicalModelComponent ∗ > ∗map, int ∗x, int ∗y, int ∗ymax, int sequenceInLine)

  Recursively rebuilds graphical items and links from one model-component branch.
- void generateGraphicalModelFromModel ()

  Rebuilds the full scene model representation from kernel source components.

Static Public Member Functions

- static void synchronizeGraphicalDataDefinitionsLayer (Simulator ∗simulator, ModelGraphicsScene ∗scene)

  Synchronizes graphical data definitions while preserving existing layout.

17.342.1 Detailed Description

Service that reconstructs graphical components/connections from kernel model data.
This builder is used after model loading to recreate the scene representation while keeping MainWindow as a compatibility façade. It acts as a model-representation bridge between the kernel component graph and GUI graphical items.
Responsibilities:

- recursively create graphical nodes/connections for component branches;
- generate a full scene representation from model source components;
- apply plugin-category visual metadata needed during reconstruction.

Boundaries:

- it does not persist files or parse textual model language;
- it does not manage selection/property editor/simulation command flows;
- it operates as a reconstruction service, not a controller.

17.342.2 Constructor & Destructor Documentation

17.342.2.1 GraphicalModelBuilder()

```
GraphicalModelBuilder::GraphicalModelBuilder (
            Simulator * simulator,
            ModelGraphicsView * graphicsView,
            ModelGraphicsScene * scene,
            std::map< std::string, QColor > * pluginCategoryColor,
            QTextEdit * console )
```

Creates the reconstruction service used by load/rebuild compatibility flows.
Builds the graphical reconstruction service with explicit dependencies.

17.342.3 Member Function Documentation

17.342.3.1 generateGraphicalModelFromModel()

```
void GraphicalModelBuilder::generateGraphicalModelFromModel ( )
```

Rebuilds the full scene model representation from kernel source components.
Rebuilds the full scene representation from the current kernel model.

17.342.3.2 recursivalyGenerateGraphicalModelFromModel()

```
void GraphicalModelBuilder::recursivalyGenerateGraphicalModelFromModel (
            ModelComponent * component,
            List< ModelComponent * > * visited,
            std::map< ModelComponent *, GraphicalModelComponent * > * map,
            int * x,
            int * y,
            int * ymax,
            int sequenceInLine )
```

Recursively rebuilds graphical items and links from one model-component branch.
Recursively rebuilds graphical items and connections from one branch.

17.342.3.3 setModelLevelFilter()

```
void GraphicalModelBuilder::setModelLevelFilter (
            unsigned int modelLevel )
```

Restricts this builder and the target scene to one ModelDataDefinition level.
Root model tabs use level 0 today. Submodel tabs will use the owner component/data definition level, so rebuilds can be reused without mixing visual scopes.

17.342.3.4 synchronizeGraphicalDataDefinitionsLayer()

```
void GraphicalModelBuilder::synchronizeGraphicalDataDefinitionsLayer (
            Simulator * simulator,
            ModelGraphicsScene * scene )  [static]
```

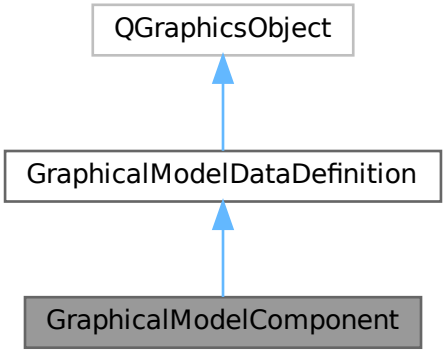
Synchronizes graphical data definitions while preserving existing layout.
Synchronizes the data-definition layer against the current kernel model.
A non-root level discovers its directly registered ModelDataDefinitions even without process components or attached/internal links. Root-level visibility retains the established process-association behavior. This does not draw mathematical Network transitions or change domain object ownership.
The documentation for this class was generated from the following files:

- applications/gui/genesys/services/GraphicalModelBuilder.h
- applications/gui/genesys/services/GraphicalModelBuilder.cpp

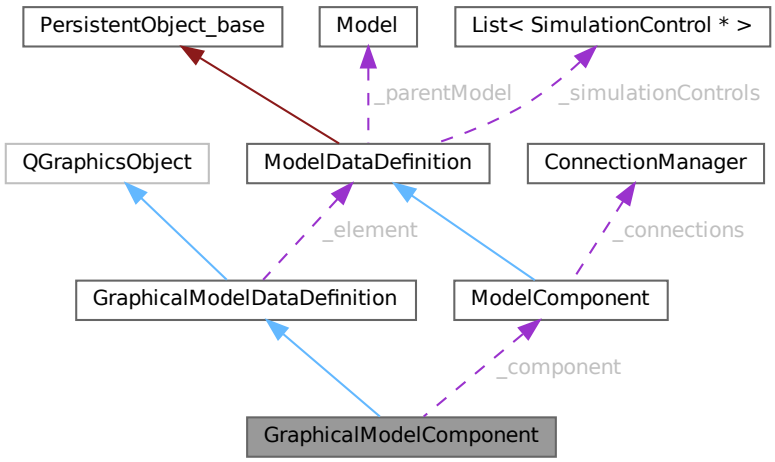
17.343 GraphicalModelComponent Class Reference

Visual component item that extends a data definition with ports and internal data.
`#include <applications/gui/genesys/graphicals/GraphicalModelComponent.h>`

Inheritance diagram for GraphicalModelComponent:



Collaboration diagram for GraphicalModelComponent:



Public Member Functions

- **GraphicalModelComponent** (Plugin *plugin, ModelComponent *component, QPointF position, QColor color=Qt::blue, QGraphicsItem *parent=nullptr)

  Creates a graphical component bound to a kernel component and plugin metadata.
- **GraphicalModelComponent** (const GraphicalModelComponent &orig)

  Copy constructor used by clipboard and restoration flows.
- virtual ~**GraphicalModelComponent** ()

  Releases the component item, including its generated port items and queues.
- QRectF **boundingRect** () const override

  Returns the rectangle used for painting and hit testing the component body.
- void **paint** (QPainter *painter, const QStyleOptionGraphicsItem *option, QWidget *widget) override

Paints the component body, ports, and selection indicators.

- ModelComponent * **getComponent** () const

  Returns the kernel component represented by this item.

- qreal **getHeight** () const

  Returns the current item height derived from the render strategy.

- QPointF **getOldPosition** () const

  Returns the previous scene position used by undo and restoration flows.

- void **setOldPosition** (QPointF oldPosition)

  Stores the previous scene position used by undo and restoration flows.

- QList< GraphicalComponentPort * > **getGraphicalInputPorts** () const

  Returns the input ports generated for this component.

- QList< GraphicalComponentPort * > **getGraphicalOutputPorts** () const

  Returns the output ports generated for this component.

- QColor **getColor** () const

  Returns the component color used by the renderer.

- void **setColor** (const QColor &color)

  Updates the component color used by the renderer.

- QList< ModelDataDefinition * > * **getInternalData** () const

  Returns the list of internal data definitions attached to the component.

- QList< ModelDataDefinition * > * **getAttachedData** () const

  Returns the list of externally attached data definitions.

- EntityType * **getEntityType** () const

  Returns the entity type synthesized or associated with the component.

- void **setEntityType** (EntityType *entityType)

  Sets the entity type synthesized or associated with the component.

- unsigned int **getOcupiedInputPorts** () const

  Returns how many input ports are currently occupied.

- unsigned int **getOcupiedOutputPorts** () const

  Returns how many output ports are currently occupied.

- void **setOcupiedInputPorts** (unsigned int value)

  Stores the number of occupied input ports tracked by the layout code.

- void **setOcupiedOutputPorts** (unsigned int value)

  Stores the number of occupied output ports tracked by the layout code.

- QString **getAnimationImageName** ()

  Returns the animation image identifier used for queue visualization.

- void **setAnimationImageName** (QString name)

  Updates the animation image identifier used by the renderer.

- QMap< Queue *, QPair< unsigned int, unsigned int > > * **getMapQueue** ()

  Returns the queue-to-metadata map used by the queue overlay renderer.

- QList< QList< GraphicalImageAnimation * > * > * **getImagesQueue** ()

  Returns the grouped queue image lists used by the renderer.

- void **verifyQueue** ()

  Verifies whether the component currently references a queue animation context.

- bool **hasQueue** ()

  Returns true when a queue animation context is available.

- unsigned int **getIndexQueue** (Queue *queue)

  Returns the queue index assigned during queue-overlay population.

- unsigned int **getSizeQueue** (Queue *queue)

  Returns the queue size recorded during queue-overlay population.

- void **populateMapQueue** (QList< Queue * > queues)

  Populates the queue overlay metadata from the supplied queue list.

- bool **insertImageQueue** (Queue *queue, GraphicalImageAnimation *image)

  Inserts one animation image entry for the given queue.
- QList< GraphicalImageAnimation * > * **removeImageQueue** (Queue *queue, unsigned int quantity↩ Removed)

  Removes a batch of animation images for the given queue.
- bool **insertImageQueue** (GraphicalImageAnimation *image)

  Inserts one animation image using the current queue context.
- GraphicalImageAnimation * **removeImageQueue** ()

  Removes the most recently inserted queue animation image.
- void **actualizeMapQueue** (Queue *queue)

  Refreshes the queue metadata after the queue model changes.
- void **visivibleImageQueue** (bool visivible)

  Shows or hides the queue image overlay.
- void **clearQueues** ()

  Clears the cached queue overlay state.

Public Member Functions inherited from GraphicalModelDataDefinition

- **GraphicalModelDataDefinition** (Plugin *plugin, ModelDataDefinition *element, QPointF position, QColor color=Qt::blue, QGraphicsItem *parent=nullptr)

  Creates one visual item bound to a kernel data definition.
- **GraphicalModelDataDefinition** (const GraphicalModelDataDefinition &orig)

  Copy constructor used by scene-copy and restore flows.
- virtual ~**GraphicalModelDataDefinition** ()

  Releases the graphical item and any owned helper state.
- QRectF **boundingRect** () const override

  Returns the item bounds used by Qt for painting and hit testing.
- QPainterPath **shape** () const override

  Returns the precise shape used for selection and collision checks.
- void **paint** (QPainter *painter, const QStyleOptionGraphicsItem *option, QWidget *widget) override

  Paints the data-definition body, label, and selection frame.
- ModelDataDefinition * **getDataDefinition** () const

  Returns the kernel data definition represented by this item.
- bool **isEditableInPropertyEditor** () const

  Returns whether the property editor may edit this item in place.
- void **setEditableInPropertyEditor** (bool editable)

  Marks the item as editable or read-only in the property editor.
- QPointF **getOldPosition** () const

  Returns the last persisted scene position before a move operation.
- void **setOldPosition** (qreal x, qreal y)

  Stores the old scene position used by undo and restoration flows.
- QColor **getColor** () const

  Returns the color used to paint the item.
- void **setColor** (QColor newColor)

  Sets the color used to paint the item.
- qreal **getHeight** () const

  Returns the height used by the current render strategy.

Static Public Member Functions

- static bool **compareQueuesById** (const Queue *a, const Queue *b)

  Compares queues by identifier so queue overlays can be ordered deterministically.

Protected Member Functions

- virtual bool sceneEvent (QEvent *event) override
- QVariant **itemChange** (GraphicsItemChange change, const QVariant &value) override
- GraphicalModelItemRenderContext renderContext () const override

17.343.1 Detailed Description

Visual component item that extends a data definition with ports and internal data.
The scene uses this class for kernel model components that need both the visual body and the connection ports used to route edges between components.

17.343.2 Member Function Documentation

17.343.2.1 renderContext()

```
GraphicalModelItemRenderContext GraphicalModelComponent::renderContext ( ) const  [override],
[protected], [virtual]
```

Reimplemented from GraphicalModelDataDefinition.

17.343.2.2 sceneEvent()

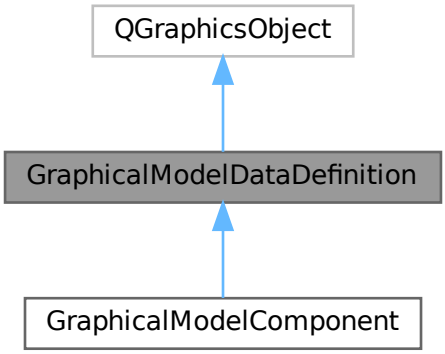
```
bool GraphicalModelComponent::sceneEvent (
            QEvent * event )  [override], [protected], [virtual]
```

Reimplemented from GraphicalModelDataDefinition.
The documentation for this class was generated from the following files:

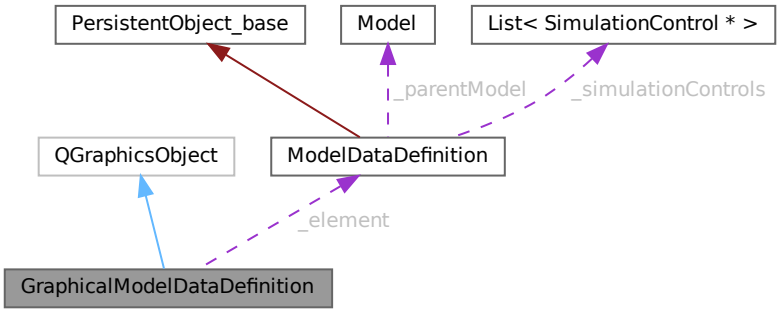
- applications/gui/genesys/graphicals/GraphicalModelComponent.h
- applications/gui/genesys/graphicals/GraphicalModelComponent.cpp

17.344 GraphicalModelDataDefinition Class Reference

Visual representation of a model data definition in the scene.
`#include <applications/gui/genesys/graphicals/GraphicalModelDataDefinition.h>`
Inheritance diagram for GraphicalModelDataDefinition:



Collaboration diagram for GraphicalModelDataDefinition:



Public Member Functions

- **GraphicalModelDataDefinition** (Plugin ∗plugin, ModelDataDefinition ∗element, QPointF position, QColor color=Qt::blue, QGraphicsItem ∗parent=nullptr)

  Creates one visual item bound to a kernel data definition.
- **GraphicalModelDataDefinition** (const GraphicalModelDataDefinition &orig)

  Copy constructor used by scene-copy and restore flows.
- virtual ∼**GraphicalModelDataDefinition** ()

  Releases the graphical item and any owned helper state.
- QRectF **boundingRect** () const override

  Returns the item bounds used by Qt for painting and hit testing.
- QPainterPath **shape** () const override

  Returns the precise shape used for selection and collision checks.
- void **paint** (QPainter ∗painter, const QStyleOptionGraphicsItem ∗option, QWidget ∗widget) override

  Paints the data-definition body, label, and selection frame.
- ModelDataDefinition ∗ **getDataDefinition** () const

  Returns the kernel data definition represented by this item.
- bool **isEditableInPropertyEditor** () const

  Returns whether the property editor may edit this item in place.
- void **setEditableInPropertyEditor** (bool editable)

  Marks the item as editable or read-only in the property editor.
- QPointF **getOldPosition** () const

  Returns the last persisted scene position before a move operation.
- void **setOldPosition** (qreal x, qreal y)

  Stores the old scene position used by undo and restoration flows.
- QColor **getColor** () const

  Returns the color used to paint the item.
- void **setColor** (QColor newColor)

  Sets the color used to paint the item.
- qreal **getHeight** () const

  Returns the height used by the current render strategy.

Protected Member Functions

- QColor **myrgba** (uint64_t color)
- virtual GraphicalModelItemRenderContext **renderContext** () const
- virtual bool **sceneEvent** (QEvent ∗event) override

Protected Attributes

17.344.1 Detailed Description

Visual representation of a model data definition in the scene.
This is the base graphical item used for non-component data definitions. Derived classes such as `GraphicalModelComponent` extend it with ports, internal data, and richer layout.
The documentation for this class was generated from the following files:

- applications/gui/genesys/graphicals/GraphicalModelDataDefinition.h
- applications/gui/genesys/graphicals/GraphicalModelDataDefinition.cpp

17.345 GraphicalModelEvent Class Reference

Lightweight event envelope used to notify GUI changes in the graphics scene.
`#include <applications/gui/genesys/graphicals/ModelGraphicsScene.h>`

Public Types

- enum class **EventType** : int {
  CREATE = 1 , **REMOVE** = 2 , **EDIT** = 3 , **CLONE** = 4 ,
  OTHER = 9 }
- enum class **EventObjectType** : int {
  COMPONENT = 1 , **DATADEFINITION** = 2 , **CONNECTION** = 3 , **DRAWING** = 4 ,
  ANIMATION = 5 , **PLOT** = 6 , **OTHER** = 9 }

Public Member Functions

- **GraphicalModelEvent** (GraphicalModelEvent::EventType eventType, GraphicalModelEvent::EventObject↩ Type eventObjectType, QGraphicsItem *item)

  Creates one event payload for the given item and event categories.

Public Attributes

- GraphicalModelEvent::EventType **eventType**
- GraphicalModelEvent::EventObjectType **eventObjectType**
- QGraphicsItem * **item**

17.345.1 Detailed Description

Lightweight event envelope used to notify GUI changes in the graphics scene.
The documentation for this class was generated from the following file:

- applications/gui/genesys/graphicals/ModelGraphicsScene.h

17.346 GraphicalModelItemRenderContext Struct Reference

17.349 GraphicalModelSerializer Class Reference

Persistence service for saving/loading graphical and textual model representations.
`#include <applications/gui/genesys/services/GraphicalModelSerializer.h>`

Public Member Functions

- GraphicalModelSerializer (Simulator *simulator, QWidget *ownerWidget, QPlainTextEdit *modelTextEditor, ModelGraphicsView *graphicsView, QSlider *zoomSlider, QAction *actionShowGrid, QAction *action↩ ShowRule, QAction *actionShowSnap, QAction *actionShowGuides, QAction *actionShowInternalElements, QAction *actionShowEditableElements, QAction *actionShowAttachedElements, QAction *actionShow↩ RecursiveElements, QTextEdit *console, QString *modelFilename, std::function< void()> clearModel↩ Editors, std::function< void()> rebuildGraphicalModelFromModel, std::function< void()> applyShow↩ InternalElements, std::function< void()> applyShowEditableElements, std::function< void()> applyShow↩ AttachedElements, std::shared_ptr< EFSMNetworkDiagramLayoutsByModel > efsmNetworkDiagram↩ Layouts=nullptr)

  Creates the persistence service that backs MainWindow lifecycle wrappers.
- bool saveTextModel (QFile *saveFile, const QString &data) const

  Saves textual model language using the established compatibility format.
- bool saveGraphicalModel (const QString &filename) const

  Saves full graphical `.gui` persistence sections without format changes.
- Model * loadGraphicalModel (const std::string &filename) const

  Loads `.gui/.gen` model files and restores persisted graphical/UI state.
- void setEFSMNetworkDiagramLayout (Model *model, unsigned long networkId, const EFSMNetworkDiagramLayout &layout)

  Sets the GUI-only EFSM diagram layout for a root model and Network on the next `saveGraphicalModel()` call. An empty layout removes any previously stored entry for that model/network pair. This never touches kernel mathematical state; see `EFSMNetworkDiagramLayout`.
- EFSMNetworkDiagramLayout efsmNetworkDiagramLayout (Model *model, unsigned long networkId) const

  Returns the EFSM diagram layout held for this model and Network id. Returns a default-constructed (empty) layout when none is known.
- void **forgetEFSMNetworkLayouts** (Model *model)

  Drops cached GUI layouts when their owning root model is closed.

17.349.1 Detailed Description

Persistence service for saving/loading graphical and textual model representations.
This Phase-2 extraction removes serialization concerns from MainWindow while preserving file compatibility through wrapper delegation. It bridges GUI state (scene/view/actions/editors) and kernel model loading/saving workflows.
Responsibilities:

- save textual model content with the existing line-based format;
- save full graphical .gui state sections used by legacy compatibility;
- load persisted model files and restore graphical/editor UI state via callbacks.

Boundaries:

- it does not own widgets or simulator lifetime;
- it does not run simulation commands or trace rendering;
- it coordinates persistence/serialization only.

17.349.2 Constructor & Destructor Documentation

17.349.2.1 GraphicalModelSerializer()

```
GraphicalModelSerializer::GraphicalModelSerializer (
            Simulator * simulator,
            QWidget * ownerWidget,
            QPlainTextEdit * modelTextEditor,
            ModelGraphicsView * graphicsView,
            QSlider * zoomSlider,
            QAction * actionShowGrid,
            QAction * actionShowRule,
            QAction * actionShowSnap,
            QAction * actionShowGuides,
            QAction * actionShowInternalElements,
            QAction * actionShowEditableElements,
            QAction * actionShowAttachedElements,
            QAction * actionShowRecursiveElements,
            QTextEdit * console,
            QString * modelFilename,
            std::function< void()> clearModelEditors,
            std::function< void()> rebuildGraphicalModelFromModel,
            std::function< void()> applyShowInternalElements,
            std::function< void()> applyShowEditableElements,
            std::function< void()> applyShowAttachedElements,
            std::shared_ptr< EFSMNetworkDiagramLayoutsByModel > efsmNetworkDiagramLayouts =
nullptr )
```

Creates the persistence service that backs MainWindow lifecycle wrappers.
Builds the serializer with explicit, narrow dependencies from MainWindow.

17.349.3 Member Function Documentation

17.349.3.1 efsmNetworkDiagramLayout()

```
EFSMNetworkDiagramLayout GraphicalModelSerializer::efsmNetworkDiagramLayout (
            Model * model,
            unsigned long networkId ) const
```

Returns the EFSM diagram layout held for this model and Network id. Returns a default-constructed (empty) layout when none is known.
Returns the EFSM diagram layout currently held for the given network.

17.349.3.2 loadGraphicalModel()

```
Model * GraphicalModelSerializer::loadGraphicalModel (
            const std::string & filename ) const
```

Loads `.gui/.gen` model files and restores persisted graphical/UI state.
Loads `.gui` or `.gen` model files and restores persisted GUI state.

Returns

Loaded kernel model pointer or nullptr when loading fails.

17.349.3.3 saveGraphicalModel()

```
bool GraphicalModelSerializer::saveGraphicalModel (
            const QString & filename ) const
```

Saves full graphical `.gui` persistence sections without format changes.
Persists the complete graphical model, including view options and overlays.

Returns

true when serialization succeeds.

17.349.3.4 saveTextModel()

```
bool GraphicalModelSerializer::saveTextModel (
            QFile * saveFile,
            const QString & data ) const
```

Saves textual model language using the established compatibility format.
Writes model text line by line using the legacy persistence format.

Returns

true when write succeeds.

17.349.3.5 setEFSMNetworkDiagramLayout()

```
void GraphicalModelSerializer::setEFSMNetworkDiagramLayout (
            Model * model,
            unsigned long networkId,
            const EFSMNetworkDiagramLayout & layout )
```

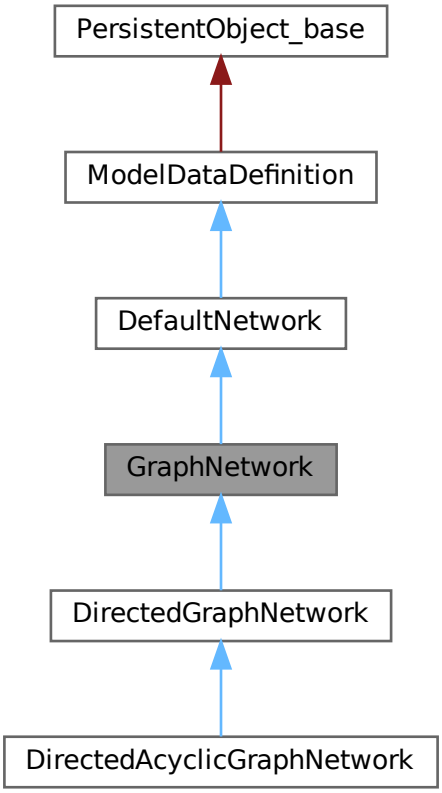
Sets the GUI-only EFSM diagram layout for a root model and Network on the next `saveGraphicalModel()` call. An empty layout removes any previously stored entry for that model/network pair. This never touches kernel mathematical state; see `EFSMNetworkDiagramLayout`.
Sets the GUI-only EFSM diagram layout to persist for the given network.
The documentation for this class was generated from the following files:

- applications/gui/genesys/services/GraphicalModelSerializer.h
- applications/gui/genesys/services/GraphicalModelSerializer.cpp

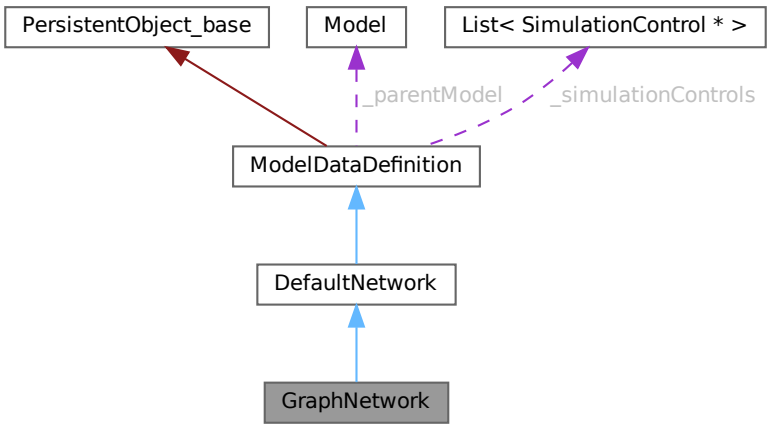
17.350 GraphNetwork Class Reference

Mathematical graph specialization of DefaultNetwork.
`#include <plugins/data/ModalModel/GraphNetwork.h>`

Inheritance diagram for GraphNetwork:



Collaboration diagram for GraphNetwork:



Public Member Functions

- **GraphNetwork** (Model *model, std::string name="", std::string dataDefinitionTypename=Util::TypeOf< GraphNetwork >())

- std::vector< GraphNode * > **reachableNodes** (GraphNode *source) const
- GraphPathResult **shortestPathUnweighted** (GraphNode *source, GraphNode *destination) const
- GraphPathResult **shortestPathDijkstra** (GraphNode *source, GraphNode *destination) const
- std::vector< std::vector< GraphNode * > > **connectedComponents** () const
- virtual bool **hasCycle** () const
- virtual GraphTopologicalOrderResult **topologicalOrder** () const
- virtual std::string show () override

  Returns a textual representation of this data definition.

Public Member Functions inherited from DefaultNetwork

- **DefaultNetwork** (Model *model, std::string name="", std::string dataDefinitionTypename=Util::TypeOf< DefaultNetwork >())
- unsigned int **addInputPort** (const std::string &portName)

  Declares a new input port; returns its 0-based index. Rejects a duplicate name (returns the existing index instead of creating a duplicate).
- unsigned int **addOutputPort** (const std::string &portName)

  Declares a new output port; returns its 0-based index. Rejects a duplicate name (returns the existing index instead of creating a duplicate).
- unsigned int **getNumInputPorts** () const
- unsigned int **getNumOutputPorts** () const
- std::string **getInputPortName** (unsigned int index) const
- std::string **getOutputPortName** (unsigned int index) const
- int **getInputPortIndex** (const std::string &portName) const

  Returns the input port index for `portName`, or -1 when not declared.
- int **getOutputPortIndex** (const std::string &portName) const

Returns the output port index for `portName`, or -1 when not declared.

- double **getActivationCount** () const

  Number of times activate() has been called since the last replication reset.

- NetworkActivationResult activate (const NetworkActivationFrame &frame)

  Runs exactly one network activation for `frame`.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.

- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.

- Util::identification getId () const

  Returns the unique identifier of this instance.

- void setName (const std::string &name)

  Updates the logical name of this instance.

- const std::string & getName () const

  Returns the logical name of this instance.

- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.

- const std::string & getLabel () const

  Returns the user-visible label of this instance.

- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.

- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.

- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.

- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.

- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.

- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.

- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.

- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.

- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.

- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.

- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static ModelDataDefinition * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static PluginInformation * **GetPluginInformation** ()
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from DefaultNetwork

- static ModelDataDefinition * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static PluginInformation * **GetPluginInformation** ()
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  must be overriden by derived classes
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes
- virtual void _initBetweenReplications () override
- virtual bool **_edgeConnects** (GraphEdge *edge, GraphNode *source, GraphNode *destination) const
- virtual GraphNode * **_oppositeNode** (GraphEdge *edge, GraphNode *node) const

Protected Member Functions inherited from DefaultNetwork

- virtual void _createInternalStatisticReporters () override
- virtual NetworkActivationResult _activate (const NetworkActivationFrame &frame)

  Formalism-specific activation behavior.

Protected Member Functions inherited from ModelDataDefinition

17.350.1 Detailed Description

Mathematical graph specialization of DefaultNetwork.
GraphNetwork represents G=(V,E) and algorithms over that topology. It is not a process network of Model↩ Component+Connection, and its inherited activation remains inert: a pure graph has no current vertex or firing/movement semantics. Dynamic traversal, random walks and routing belong to future explicit specializations/adapters.
Algorithms use insertion-order adjacency for deterministic behavior: BFS/DFS/connected components/cycle detection are O(V+E); unweighted shortest path is BFS O(V+E); Dijkstra with the simple implementation here is O(V^2+E). Temporary visited, predecessor, queue, stack and distance data are local to each algorithm call and are never persisted.

17.350.2 Member Function Documentation

17.350.2.1 _check()

```
bool GraphNetwork::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from DefaultNetwork.
Reimplemented in DirectedAcyclicGraphNetwork.

17.350.2.2 _initBetweenReplications()

```
void GraphNetwork::_initBetweenReplications ( )  [override], [protected], [virtual]
```

Reimplemented from DefaultNetwork.

17.350.2.3 _loadInstance()

```
bool GraphNetwork::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from DefaultNetwork.

17.350.2.4 _saveInstance()

```
void GraphNetwork::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from DefaultNetwork.

17.350.2.5 show()

`std::string GraphNetwork::show ( ) [override], [virtual]`
Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from DefaultNetwork.
The documentation for this class was generated from the following files:

- plugins/data/ModalModel/GraphNetwork.h
- plugins/components/ModalModel/GraphNetwork.cpp

17.351 GraphNode Class Reference

Mathematical graph vertex used by GraphNetwork.

  virtual public methods

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model ∗model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ∼**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.

- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelDataDefinition * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from DefaultNode

- static PluginInformation * **GetPluginInformation** ()

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static ModelDataDefinition * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Additional Inherited Members

Protected Member Functions inherited from DefaultNode

17.351.1 Detailed Description

Mathematical graph vertex used by GraphNetwork.
A GraphNode is a model data definition, not a process ModelComponent. It reuses DefaultNode's persistable identity/name/flag infrastructure without inheriting process-flow Connection semantics.
The documentation for this class was generated from the following files:

- plugins/data/ModalModel/GraphNode.h
- plugins/components/ModalModel/GraphNode.cpp

17.352 GraphPathResult Struct Reference

Explicit graph path result.
`#include <plugins/data/ModalModel/GraphNetwork.h>`

Public Attributes

- bool **reachable** = false
- double **distance** = 0.0
- std::vector< GraphNode * > **nodes**
- std::vector< GraphEdge * > **edges**
- std::string **errorMessage** = ""

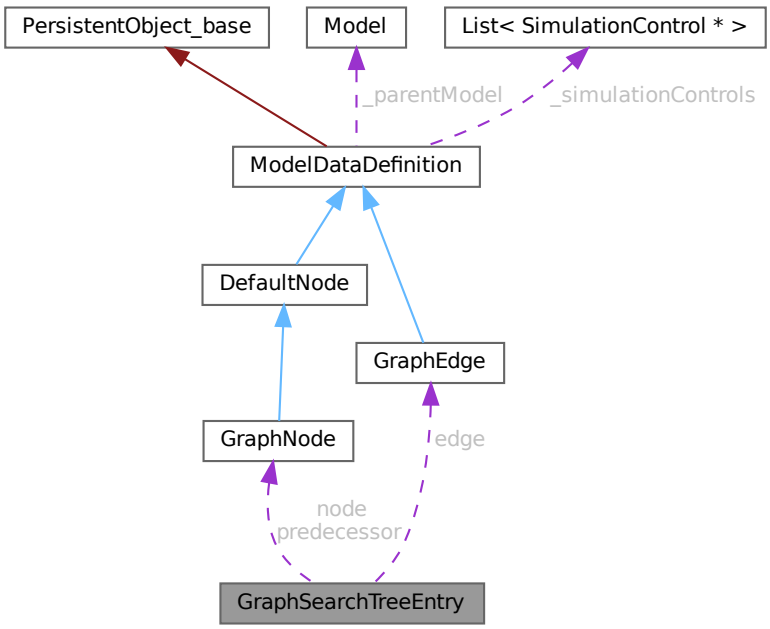
17.352.1 Detailed Description

Explicit graph path result.
`reachable=false` represents absence of a path. `errorMessage` reports rejected operations such as Dijkstra over negative-weight edges.
The documentation for this struct was generated from the following file:

- plugins/data/ModalModel/GraphNetwork.h

17.353 GraphSearchTreeEntry Struct Reference

Collaboration diagram for GraphSearchTreeEntry:



Public Attributes

- GraphNode * **node** = nullptr
- GraphNode * **predecessor** = nullptr
- GraphEdge * **edge** = nullptr

- unsigned int **distance** = 0

The documentation for this struct was generated from the following file:

- plugins/data/ModalModel/GraphNetwork.h

17.354 GraphTopologicalOrderResult Struct Reference

Public Attributes

- bool **acyclic** = false
- std::vector< GraphNode * > **order**
- std::string **errorMessage** = ""

The documentation for this struct was generated from the following file:

- plugins/data/ModalModel/GraphNetwork.h

17.355 GraphTraversalResult Struct Reference

Result of a deterministic graph traversal.
`#include <plugins/data/ModalModel/GraphNetwork.h>`

Public Member Functions

- bool **visited** (GraphNode *node) const
- GraphNode * **predecessorOf** (GraphNode *node) const
- GraphEdge * **edgeTo** (GraphNode *node) const
- unsigned int **distanceTo** (GraphNode *node) const

Public Attributes

- std::vector< GraphNode * > **visitOrder**
- std::vector< GraphSearchTreeEntry > **tree**

17.355.1 Detailed Description

Result of a deterministic graph traversal.
The traversal order follows node/edge insertion order. Temporary search structures are not persisted in GraphNetwork.
The documentation for this struct was generated from the following files:

- plugins/data/ModalModel/GraphNetwork.h
- plugins/components/ModalModel/GraphNetwork.cpp

17.356 GraphvizModelExporter Class Reference

Service that builds DOT content and renders model images for the GUI.
`#include <applications/gui/genesys/services/GraphvizModelExporter.h>`

Public Member Functions

- **GraphvizModelExporter** (Simulator *simulator, QLabel *modelGraphicLabel, QCheckBox *showStatistics, QCheckBox *showEditable, QCheckBox *showShared, QCheckBox *showRecursive, QCheckBox *showLevels, std::function< bool()> ensureModelSynchronized)

  Creates the Graphviz exporter service used by MainWindow compatibility wrappers.
- std::string adjustDotName (std::string name) const

Normalizes identifiers to Graphviz-safe names.

- void **insertTextInDot** (std::string text, unsigned int compLevel, unsigned int compRank, std::map< unsigned int, std::map< unsigned int, std::list< std::string > * > * > *dotmap, bool isNode=false) const

  Inserts a DOT line into the hierarchical rank/level map used for image generation.

- void **recursiveCreateModelGraphicPicture** (ModelDataDefinition *componentOrData, std::list< ModelDataDefinition * > *visited, std::map< unsigned int, std::map< unsigned int, std::list< std::string > * > * > *dotmap) const

  Recursively traverses model/data nodes to build DOT content fragments.

- bool createModelImage () const

  Generates and displays the model image after synchronization preconditions.

17.356.1 Detailed Description

Service that builds DOT content and renders model images for the GUI.
This service encapsulates Graphviz-oriented model representation logic extracted from MainWindow. It keeps image-generation behavior stable while MainWindow exposes compatibility wrappers used by actions and tabs.
Responsibilities:

- normalize identifiers for DOT compatibility;
- build hierarchical DOT fragments from model/data-definition traversal;
- generate and display model images after ensuring text/model synchronization.

Boundaries:

- it does not own model synchronization policy (uses injected callback);
- it does not manage simulation commands, traces, or lifecycle actions;
- it provides export/representation service behavior, not controller orchestration.

17.356.2 Member Function Documentation

17.356.2.1 adjustDotName()

```
std::string GraphvizModelExporter::adjustDotName (
            std::string name ) const
```

Normalizes identifiers to Graphviz-safe names.

Parameters

name	Raw label/name from model representation.

Returns

DOT-safe identifier preserving compatibility naming intent.

17.356.2.2 createModelImage()

```
bool GraphvizModelExporter::createModelImage ( ) const
```

Generates and displays the model image after synchronization preconditions.

Returns

true when DOT generation and image rendering complete successfully.

The documentation for this class was generated from the following files:

- applications/gui/genesys/services/GraphvizModelExporter.h
- applications/gui/genesys/services/GraphvizModelExporter.cpp

17.357 ModelGraphicsScene::GRID Struct Reference

Public Member Functions

- void **clear** ()

Public Attributes

- unsigned int **interval**

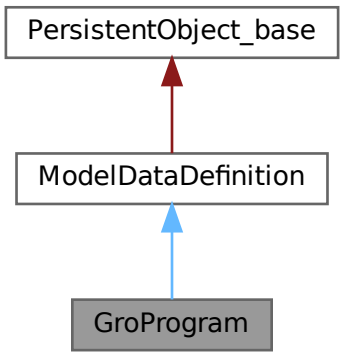
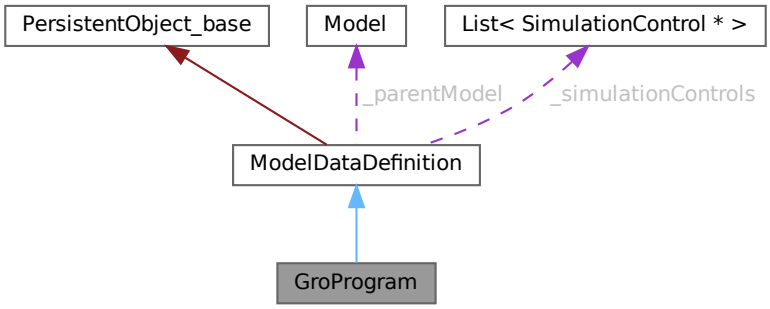
17.358 GroProgram Class Reference

Reusable Gro source program attached to a GenESyS model.
`#include <plugins/data/BiochemicalSimulation/GroProgram.h>`
Inheritance diagram for GroProgram:



Collaboration diagram for GroProgram:



Public Member Functions

- **GroProgram** (Model *model, std::string name="")
- virtual std::string show () override

  Returns a textual representation of this data definition.
- void **setSourceCode** (std::string sourceCode)

  Replaces the stored Gro source text.
- void **setSourceCodeProperty** (SourceCodeString sourceCode)

  Replaces the stored Gro source text through the property-editor wrapper type.
- std::string **getSourceCode** () const

  Returns the stored Gro source text.
- SourceCodeString **getSourceCodeProperty** () const

  Returns the stored Gro source text wrapped for the property editor.
- bool **createDefaultGroProgram** (const std::string &filename="")

  Creates a small starter Gro program and optionally writes it to a file.
- bool **validateSyntax** (std::string &errorMessage) const

  Performs a permissive lexical sanity check for the stored source.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.

- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

17.358.1 Detailed Description

Reusable Gro source program attached to a GenESyS model.
GroProgram is intentionally a ModelDataDefinition so several biological components can share the same Gro source text. This first implementation only stores the source and performs a small lexical sanity check; complete Gro parsing and executable semantics belong to later plugin-side helper classes.

17.358.2 Member Function Documentation

17.358.2.1 _check()

```
bool GroProgram::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.358.2.2 _loadInstance()

```
bool GroProgram::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.358.2.3 _saveInstance()

```
void GroProgram::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.

17.358.2.4 show()

```
std::string GroProgram::show ( )  [override], [virtual]
```

Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from ModelDataDefinition.
The documentation for this class was generated from the following files:

- plugins/data/BiochemicalSimulation/GroProgram.h
- plugins/data/BiochemicalSimulation/GroProgram.cpp

17.359 GroProgramAst Struct Reference

Minimal parsed representation of a Gro source program.
`#include <plugins/data/BiochemicalSimulation/GroProgramAst.h>`

Classes

- struct NamedProgram
- struct Statement

Public Types

- enum class **SourceForm** { **RawStatements** , **ProgramBlock** }

Public Member Functions

- bool **isProgramBlock** () const
- bool **hasNamedPrograms** () const

Public Attributes

- SourceForm **sourceForm** = SourceForm::RawStatements
- std::string **programName** = ""
- std::vector< std::string > **programParameters**
- std::string **bodySource** = ""
- std::vector< Statement > **statements**
- std::vector< NamedProgram > **namedPrograms**

17.359.1 Detailed Description

Minimal parsed representation of a Gro source program.
This AST intentionally models only the first integration target: either a recognized `program name() { ... }` block or a permissive raw statement list. Execution semantics and typed Gro constructs belong to later phases.
The documentation for this struct was generated from the following file:

- plugins/data/BiochemicalSimulation/GroProgramAst.h

17.360 GroProgramCompiler Class Reference

Converts parsed Gro AST into the first non-executable semantic IR.
`#include <plugins/data/BiochemicalSimulation/GroProgramCompiler.h>`

Public Member Functions

- GroProgramIr **compile** (const GroProgramAst &ast) const

  Builds a lightweight semantic IR from a parsed Gro AST.

17.360.1 Detailed Description

Converts parsed Gro AST into the first non-executable semantic IR.
The documentation for this class was generated from the following files:

- plugins/data/BiochemicalSimulation/GroProgramCompiler.h
- plugins/data/BiochemicalSimulation/GroProgramCompiler.cpp

17.361 GroProgramIr Struct Reference

Initial semantic representation compiled from GroProgramAst.
`#include <plugins/data/BiochemicalSimulation/GroProgramIr.h>`

Classes

- struct Command
- struct NamedProgramDefinition

Public Member Functions

- bool **isProgramBlock** () const
- bool **hasNamedProgram** (const std::string &name) const

Public Attributes

- GroProgramAst::SourceForm **sourceForm** = GroProgramAst::SourceForm::RawStatements
- std::string **programName** = ""
- std::vector< Command > **commands**
- std::map< std::string, NamedProgramDefinition > **namedPrograms**

17.361.1 Detailed Description

Initial semantic representation compiled from GroProgramAst.
The IR keeps the parsed program in a runtime-oriented shape. It can represent function calls, assignments, and basic conditional blocks without pushing any knowledge into the simulator kernel itself.
The documentation for this struct was generated from the following file:

- plugins/data/BiochemicalSimulation/GroProgramIr.h

17.362 GroProgramParser Class Reference

Plugin-side parser boundary for reusable Gro source programs.
`#include <plugins/data/BiochemicalSimulation/GroProgramParser.h>`

Classes

- struct Result

Public Member Functions

- Result **parse** (const std::string &sourceCode) const

  Parses a Gro source string using the current lexical boundary.

17.362.1 Detailed Description

Plugin-side parser boundary for reusable Gro source programs.
This helper currently preserves the permissive lexical validation that used to live inside GroProgram. It is intentionally small so later phases can grow a real grammar, AST, and semantic checks without changing GroProgram storage.
The documentation for this class was generated from the following files:

- plugins/data/BiochemicalSimulation/GroProgramParser.h
- plugins/data/BiochemicalSimulation/GroProgramParser.cpp

17.363 GroProgramRuntime Class Reference

Executes the supported Gro IR commands without simulator binding.
`#include <plugins/data/BiochemicalSimulation/GroProgramRuntime.h>`

Classes

- struct ColonyMutation
- struct ExecutionResult
- struct MotionMutation
- struct PopulationMutation
- struct SignalMutation

Public Types

- enum class **PopulationMutationType** { **Grow** , **Divide** , **Die** , **SetPopulation** }
- enum class **SignalMutationType** { **Emit** , **Consume** , **Set** }
- enum class **MotionMutationType** { **Run** , **Tumble** }

Public Member Functions

- ExecutionResult **execute** (const GroProgramIr &ir, GroProgramRuntimeState &state) const

  Executes supported commands and reports unsupported commands.

Static Public Member Functions

- static bool validateSignalDeclarationPlacement (const GroProgramIr &ir, std::string &errorMessage)
- static bool **evaluateExpression** (const std::string &expressionText, const GroProgramRuntimeState &state, double &value, std::string &errorMessage)

  Evaluates one scalar Gro expression against one runtime state.

17.363.1 Detailed Description

Executes the supported Gro IR commands without simulator binding.
This helper is intentionally independent from BacteriaColony and the GenESyS event scheduler. It now supports persistent scalar variables, arithmetic expressions, and basic `if/else` control flow while still keeping the runtime local to the biological plugins.

17.363.2 Member Function Documentation

17.363.2.1 validateSignalDeclarationPlacement()

```
bool GroProgramRuntime::validateSignalDeclarationPlacement (
            const GroProgramIr & ir,
            std::string & errorMessage )  [static]
```

Reject structurally conditional signal declarations across all IR scopes.
The documentation for this class was generated from the following files:

- plugins/data/BiochemicalSimulation/GroProgramRuntime.h
- plugins/data/BiochemicalSimulation/GroProgramRuntime.cpp

17.364 GroProgramRuntimeState Struct Reference

Mutable state used by the plugin-side Gro runtime helper.
`#include <plugins/data/BiochemicalSimulation/GroProgramRuntime.h>`

Public Attributes

- double **colonyTime** = 0.0
- double **simulationStep** = 1.0
- unsigned int **populationSize** = 1
- unsigned int **tickCount** = 0
- std::map< std::string, double > **contextVariables**
- std::map< std::string, double > **variables**
- std::function< bool(double &, std::string &)> **sampleUnitInterval**
- unsigned int **signalDeclarationOrdinal** = 0
- unsigned int **knownSignalChannelCount** = 0
- std::string **signalDeclarationScope**

17.364.1 Detailed Description

Mutable state used by the plugin-side Gro runtime helper.
The documentation for this struct was generated from the following file:

- plugins/data/BiochemicalSimulation/GroProgramRuntime.h

17.365 GroupItem Struct Reference

Public Attributes

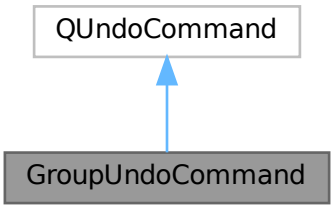
- QGraphicsItemGroup * **group**
- QList< ComponentItem > **myComponentItems**
- QPointF **initialPosition**

The documentation for this struct was generated from the following file:

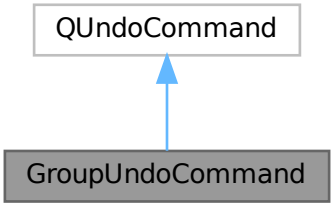
- applications/gui/genesys/actions/AddUndoCommand.h

17.366 GroupUndoCommand Class Reference

Inheritance diagram for GroupUndoCommand:



Collaboration diagram for GroupUndoCommand:



Public Member Functions

- **GroupUndoCommand** (QList< GraphicalModelComponent * > graphicalComponents, ModelGraphicsScene *scene, QUndoCommand *parent=nullptr)
- void **undo** () override
- void **redo** () override

The documentation for this class was generated from the following files:

- applications/gui/genesys/actions/GroupUndoCommand.h
- applications/gui/genesys/actions/GroupUndoCommand.cpp

17.367 testing::internal::GTestFlagSaver Class Reference

The documentation for this class was generated from the following file:

- gtest/src/gtest-internal-inl.h

17.368 testing::internal::GTestLog Class Reference

Public Member Functions

- **GTestLog** (GTestLogSeverity severity, const char *file, int line)

- ::std::ostream & **GetStream** ()

The documentation for this class was generated from the following files:

- gtest/gtest/internal/gtest-port.h
- gtest/src/gtest-port.cc

17.369 testing::internal::GTestMutexLock Class Reference

Public Member Functions

- **GTestMutexLock** (Mutex ∗)

The documentation for this class was generated from the following file:

- gtest/gtest/internal/gtest-port.h

17.370 GuiActionContribution Struct Reference

Public Attributes

- std::string **id**
- std::string **text**
- std::string **menuPath**
- std::string **toolBarId**
- std::string **statusTip**
- std::string **shortcut**
- std::function< bool(const GuiExtensionRuntimeContext &)> **isVisible**
- std::function< bool(const GuiExtensionRuntimeContext &)> **isEnabled**
- std::function< void(const GuiExtensionRuntimeContext &)> **trigger**

The documentation for this struct was generated from the following file:

- applications/gui/genesys/extensions/GuiExtensionContracts.h

17.371 GuiDockContribution Struct Reference

Public Attributes

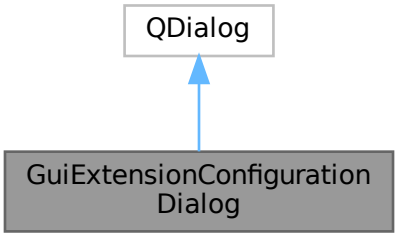
- std::string **id**
- std::string **title**
- std::string **areaHint**
- std::function< bool(const GuiExtensionRuntimeContext &)> **isVisible**
- std::function< QWidget ∗(const GuiExtensionRuntimeContext &)> **createWidget**

The documentation for this struct was generated from the following file:

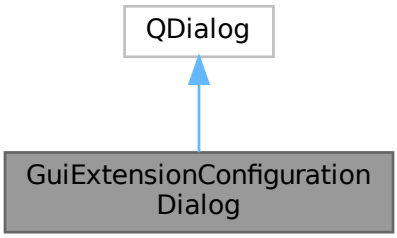
- applications/gui/genesys/extensions/GuiExtensionContracts.h

17.372 GuiExtensionConfigurationDialog Class Reference

Inheritance diagram for GuiExtensionConfigurationDialog:



Collaboration diagram for GuiExtensionConfigurationDialog:



Public Member Functions

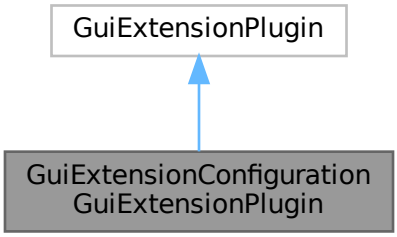
- **GuiExtensionConfigurationDialog** (QWidget ∗parent, std::vector< const GuiExtensionPlugin ∗ > plugins, std::function< void()> onSaved={})

The documentation for this class was generated from the following files:

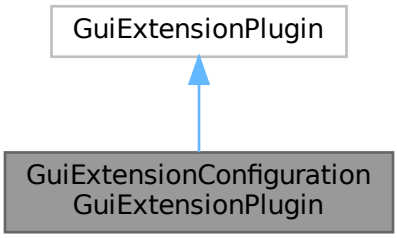
- applications/gui/genesys/extensions/GuiExtensionConfigurationDialog.h
- applications/gui/genesys/extensions/GuiExtensionConfigurationDialog.cpp

17.373 GuiExtensionConfigurationGuiExtensionPlugin Class Reference

Inheritance diagram for GuiExtensionConfigurationGuiExtensionPlugin:



Collaboration diagram for GuiExtensionConfigurationGuiExtensionPlugin:



Public Member Functions

- std::string extensionId () const override
- std::string displayName () const override
- std::string version () const override
- std::vector< std::string > requiredModelPlugins () const override
- void registerContributions (GuiExtensionRegistry *registry) const override

17.373.1 Member Function Documentation

17.373.1.1 displayName()

```
std::string GuiExtensionConfigurationGuiExtensionPlugin::displayName ( ) const  [inline],
[override], [virtual]
```

Implements GuiExtensionPlugin.

17.373.1.2 extensionId()

```
std::string GuiExtensionConfigurationGuiExtensionPlugin::extensionId ( ) const  [inline],
[override], [virtual]
```

Implements GuiExtensionPlugin.

17.373.1.3 registerContributions()

```
void GuiExtensionConfigurationGuiExtensionPlugin::registerContributions (
            GuiExtensionRegistry * registry ) const  [inline], [override], [virtual]
```

Implements GuiExtensionPlugin.

17.373.1.4 requiredModelPlugins()

```
std::vector< std::string > GuiExtensionConfigurationGuiExtensionPlugin::requiredModelPlugins (
) const  [inline], [override], [virtual]
```

Implements GuiExtensionPlugin.

17.373.1.5 version()

```
std::string GuiExtensionConfigurationGuiExtensionPlugin::version ( ) const  [inline], [override],
[virtual]
```

Implements GuiExtensionPlugin.

The documentation for this class was generated from the following file:

- applications/gui/genesys/extensions/GuiExtensionConfigurationGuiExtensionPlugin.cpp

17.374 GuiExtensionManager Class Reference

Public Member Functions

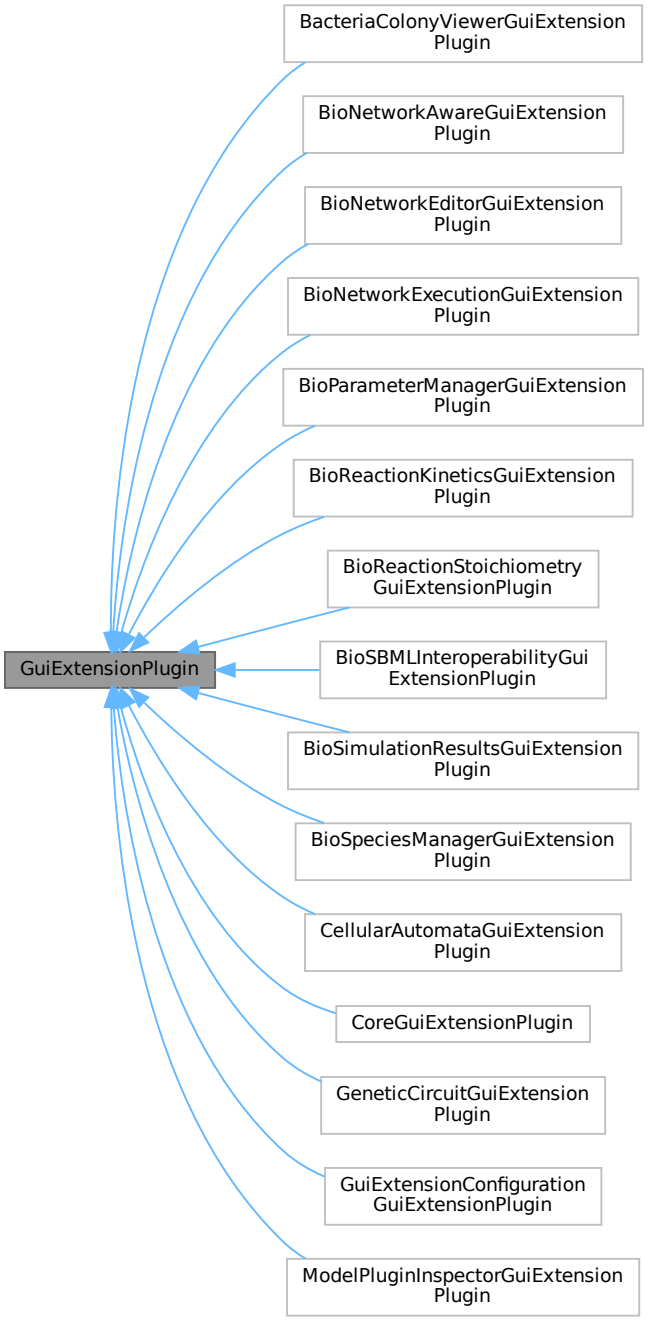
- **GuiExtensionManager** (QMainWindow ∗mainWindow)
- void **setPlugins** (std::vector< const GuiExtensionPlugin ∗ > plugins)
- void **setLoadedModelPluginIds** (std::vector< std::string > modelPluginIds)
- void **rebuild** (const GuiExtensionRuntimeContext &context)
- void **clear** ()

The documentation for this class was generated from the following files:

- applications/gui/genesys/extensions/GuiExtensionManager.h
- applications/gui/genesys/extensions/GuiExtensionManager.cpp

17.375 GuiExtensionPlugin Class Reference

Inheritance diagram for GuiExtensionPlugin:



Public Member Functions

- virtual std::string **extensionId** () const =0
- virtual std::string **displayName** () const =0
- virtual std::string **version** () const =0
- virtual std::vector< std::string > **requiredModelPlugins** () const =0
- virtual void **registerContributions** (GuiExtensionRegistry *registry) const =0

The documentation for this class was generated from the following file:

- applications/gui/genesys/extensions/GuiExtensionContracts.h

17.376 GuiExtensionPluginAutoRegistrar Class Reference

Public Member Functions

- **GuiExtensionPluginAutoRegistrar** (const GuiExtensionPlugin *plugin)

The documentation for this class was generated from the following files:

- applications/gui/genesys/extensions/GuiExtensionPluginCatalog.h
- applications/gui/genesys/extensions/GuiExtensionPluginCatalog.cpp

17.377 GuiExtensionPluginCatalog Class Reference

Static Public Member Functions

- static const std::vector< const GuiExtensionPlugin * > & **plugins** ()
- static std::vector< const GuiExtensionPlugin * > **resolvedPlugins** ()
- static GuiExtensionPresentationMetadata **presentationMetadata** (const std::string &extensionId)
- static void **registerPlugin** (const GuiExtensionPlugin *plugin)

The documentation for this class was generated from the following files:

- applications/gui/genesys/extensions/GuiExtensionPluginCatalog.h
- applications/gui/genesys/extensions/GuiExtensionPluginCatalog.cpp

17.378 GuiExtensionPresentationMetadata Struct Reference

Public Attributes

- std::string **category**
- std::string **group**
- int **priority** = 0

The documentation for this struct was generated from the following file:

- applications/gui/genesys/extensions/GuiExtensionPluginCatalog.h

17.379 GuiExtensionRegistry Class Reference

Public Member Functions

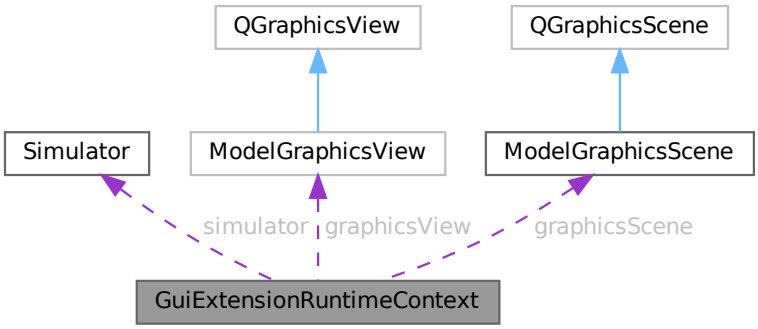
- void **addAction** (GuiActionContribution contribution)
- void **addDock** (GuiDockContribution contribution)
- void **addWindow** (GuiWindowContribution contribution)
- const std::vector< GuiActionContribution > & **actions** () const
- const std::vector< GuiDockContribution > & **docks** () const
- const std::vector< GuiWindowContribution > & **windows** () const
- void **clear** ()

The documentation for this class was generated from the following file:

- applications/gui/genesys/extensions/GuiExtensionContracts.h

17.380 GuiExtensionRuntimeContext Struct Reference

Collaboration diagram for GuiExtensionRuntimeContext:



Public Attributes

- Simulator * **simulator** = nullptr
- QMainWindow * **mainWindow** = nullptr
- Ui::MainWindow * **ui** = nullptr
- ModelGraphicsView * **graphicsView** = nullptr
- ModelGraphicsScene * **graphicsScene** = nullptr

The documentation for this struct was generated from the following file:

- applications/gui/genesys/extensions/GuiExtensionContracts.h

17.381 GuiScopeTrace Class Reference

Emits a scoped trace entry for a GUI method and measures its runtime.
`#include <applications/gui/genesys/GuiScopeTrace.h>`

Public Member Functions

- GuiScopeTrace (const char *methodName, const void *thisPtr)

  Starts a scoped GUI trace entry for a critical method invocation.
- ~**GuiScopeTrace** ()

  Ends the scoped trace and logs the elapsed execution time.

17.381.1 Detailed Description

Emits a scoped trace entry for a GUI method and measures its runtime.
Instances are usually created on the stack at the beginning of a method so the constructor logs entry and the destructor logs the elapsed time when the scope exits.

17.381.2 Constructor & Destructor Documentation

17.381.2.1 GuiScopeTrace()

```
GuiScopeTrace::GuiScopeTrace (
            const char * methodName,
            const void * thisPtr )
```

Starts a scoped GUI trace entry for a critical method invocation.

Parameters

methodName	Name of the traced method.
thisPtr	Pointer to the current object, when available.

The documentation for this class was generated from the following files:

- applications/gui/genesys/GuiScopeTrace.h
- applications/gui/genesys/GuiScopeTrace.cpp

17.382 GuiThemeManager Class Reference

Applies the visual theme used by the Qt application and model views.
`#include <applications/gui/genesys/guithememanager.h>`

Static Public Member Functions

- static void applyApplicationTheme (QApplication ∗application)

  Applies application-wide theme settings to the Qt application object.
- static void applyModelGraphicsTheme (ModelGraphicsView ∗graphicsView)

  Applies the model-graphics theme to a specific graphics view.

17.382.1 Detailed Description

Applies the visual theme used by the Qt application and model views.
The theme manager centralizes palette-level adjustments so the application and graphics scene remain visually consistent when preferences change.

17.382.2 Member Function Documentation

17.382.2.1 applyApplicationTheme()

```
void GuiThemeManager::applyApplicationTheme (
            QApplication * application )  [static]
```

Applies application-wide theme settings to the Qt application object.

Parameters

application	Target QApplication instance.

17.382.2.2 applyModelGraphicsTheme()

```
void GuiThemeManager::applyModelGraphicsTheme (
            ModelGraphicsView * graphicsView )  [static]
```

Applies the model-graphics theme to a specific graphics view.

Parameters

graphicsView	Target graphics view.

The documentation for this class was generated from the following files:

- applications/gui/genesys/guithememanager.h
- applications/gui/genesys/guithememanager.cpp

17.383 GuiWindowContribution Struct Reference

Public Attributes

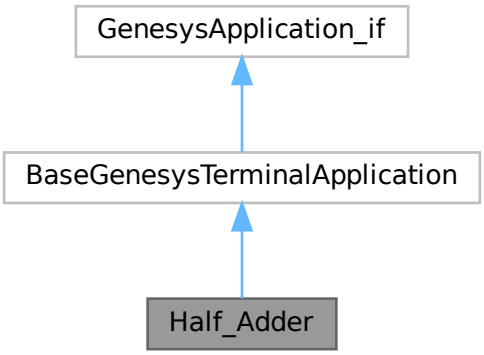
- std::string **id**
- std::string **menuPath**
- std::string **text**
- std::function< bool(const GuiExtensionRuntimeContext &)> **isVisible**
- std::function< void(const GuiExtensionRuntimeContext &)> **open**

The documentation for this struct was generated from the following file:

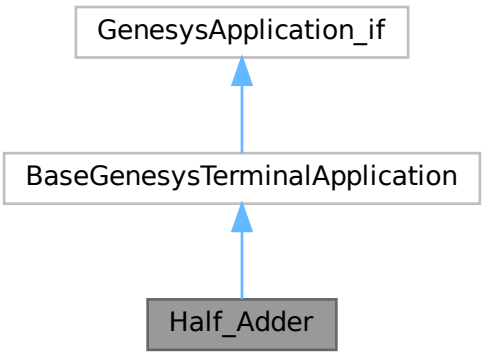
- applications/gui/genesys/extensions/GuiExtensionContracts.h

17.384 Half_Adder Class Reference

Inheritance diagram for Half_Adder:



Collaboration diagram for Half_Adder:



Public Member Functions

- virtual int main (int argc, char **argv) override

Public Member Functions inherited from BaseGenesysTerminalApplication

- virtual void **Simulate** (Simulator *genesys, Model *model, PluginManager *plugins)
- void **setDefaultTraceHandlers** (TraceManager *tm)
- void setDefaultEventHandlers (OnEventManager *oem)

Additional Inherited Members

Protected Member Functions inherited from BaseGenesysTerminalApplication

- virtual void **traceHandler** (TraceEvent e)
- virtual void **traceErrorHandler** (TraceErrorEvent e)
- virtual void **traceReportHandler** (TraceEvent e)
- virtual void **traceSimulationHandler** (TraceSimulationEvent e)
- virtual void **onAfterProcessEventHandler** (SimulationEvent *re)
- virtual void **onBreakpointHandler** (SimulationEvent *re)
- virtual void **onEntityCreateHandler** (SimulationEvent *re)
- virtual void **onEntityMoveHandler** (SimulationEvent *re)
- virtual void **onSimulationStartHandler** (SimulationEvent *re)
- virtual void **onReplicationStepHandler** (SimulationEvent *re)
- virtual void **onReplicationStartHandler** (SimulationEvent *re)
- virtual void **onProcessEventHandler** (SimulationEvent *re)
- virtual void **onReplicationEndHandler** (SimulationEvent *re)
- virtual void **onSimulationEndHandler** (SimulationEvent *re)
- virtual void **onSimulationPausedHandler** (SimulationEvent *re)
- virtual void **onSimulationResumeHandler** (SimulationEvent *re)
- virtual void **onEntityRemoveHandler** (SimulationEvent *re)

17.384.1 Member Function Documentation

17.384.1.1 main()

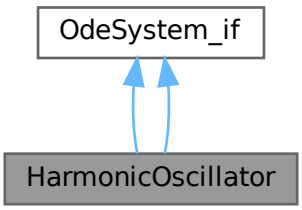
```
int Half_Adder::main (
            int argc,
            char ** argv )  [override], [virtual]
```

This is the main function of the application. It instanciates the simulator, builds a simulation model and then simulate that model.
Reimplemented from BaseGenesysTerminalApplication.
The documentation for this class was generated from the following files:

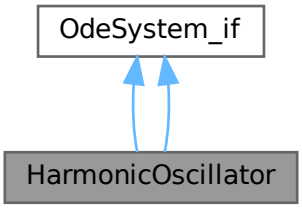
- applications/modelSpecific/teaching/Half_Adder.h
- applications/modelSpecific/teaching/Half_Adder.cpp

17.385 HarmonicOscillator Class Reference

Inheritance diagram for HarmonicOscillator:



Collaboration diagram for HarmonicOscillator:



Public Member Functions

- unsigned int dimension () const override
- void evaluate (double t, const double *y, double *dydt) const override

17.385.1 Member Function Documentation

17.385.1.1 dimension()

```
unsigned int HarmonicOscillator::dimension ( ) const  [inline], [override], [virtual]
```

Implements OdeSystem_if.

17.385.1.2 evaluate()

```
void HarmonicOscillator::evaluate (
            double t,
            const double * y,
            double * dydt ) const  [inline], [override], [virtual]
```

Implements OdeSystem_if.

The documentation for this class was generated from the following file:

- tests/test_ode_solver_numerical_validation.cpp

17.386 testing::internal::HasDebugStringAndShortDebugString< T > Class Template Reference

Static Public Attributes

- static constexpr bool value

17.386.1 Member Data Documentation

17.386.1.1 value

```
template<typename T >
constexpr bool testing::internal::HasDebugStringAndShortDebugString< T >::value  [static],
[constexpr]
```

Initial value:

```
=
      HasDebugStringType::value && HasShortDebugStringType::value
```

The documentation for this class was generated from the following file:

```
bool HppLatticeGasStateSet::isComposite ( ) const  [inline], [override], [virtual]
```

Reimplemented from StateSet.

17.389.1.5 isDiscrete()

```
bool HppLatticeGasStateSet::isDiscrete ( ) const  [inline], [override], [virtual]
```

Reimplemented from StateSet.

17.389.1.6 isFinite()

```
bool HppLatticeGasStateSet::isFinite ( ) const  [inline], [override], [virtual]
```

Reimplemented from StateSet.

17.389.1.7 name()

```
std::string HppLatticeGasStateSet::name ( ) const  [inline], [override], [virtual]
```

Reimplemented from StateSet.

17.389.1.8 parseState()

```
std::unique_ptr< State > HppLatticeGasStateSet::parseState (
            const std::string & text ) const  [inline], [override], [virtual]
```

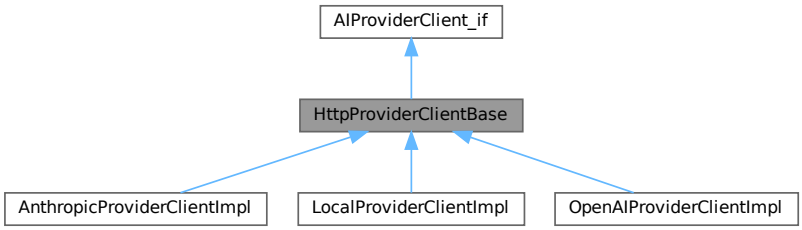
Reimplemented from StateSet.

The documentation for this class was generated from the following file:

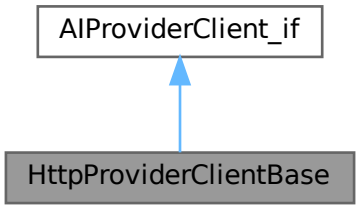
- plugins/components/ModalModel/CellularAutomata/StateSet.h

17.390 HttpProviderClientBase Class Reference

Abstract base class for HTTP-based AI provider clients.
`#include <tools/AIAssistant/HttpProviderClientBase.h>`
Inheritance diagram for HttpProviderClientBase:



Collaboration diagram for HttpProviderClientBase:



Public Member Functions

- **HttpProviderClientBase** (const HttpProviderClientBase &)=delete
- HttpProviderClientBase & **operator=** (const HttpProviderClientBase &)=delete
- bool isAvailable () const override

  Returns `true` when this client can attempt to send requests.
- void setBaseUrl (const std::string &url) override

  Sets the base URL for the provider API endpoint.
- std::string getBaseUrl () const override

  Returns the currently configured base URL.
- void setTimeoutSeconds (unsigned int seconds) override

  Sets the HTTP request timeout in seconds.
- unsigned int getTimeoutSeconds () const override

  Returns the configured HTTP request timeout.
- void setApiKey (const std::string &apiKey) override

  Stores the API key in memory.
- void clearApiKey () override

  Overwrites (best-effort) and clears the in-memory API key.
- bool hasApiKey () const override

  Returns `true` when a non-empty API key is held.

- ProviderResponse send (const ProviderRequest &request) override

  Executes the HTTP request via curl and returns the provider response.

Public Member Functions inherited from AIProviderClient_if

- virtual std::string getProviderName () const =0

  Returns a human-readable provider name (e.g. "OpenAI", "Anthropic").

Static Public Member Functions

- static std::string **_escapeJsonString** (const std::string &s)

  Escapes a plain string for safe embedding inside a JSON string value.
- static std::string **_extractJsonString** (const std::string &json, const std::string &key)

  Extracts the value of a top-level JSON string field by key. Returns an empty string when not found or value is not a quoted string.
- static int **_extractJsonInt** (const std::string &json, const std::string &key)

  Extracts the value of a top-level JSON integer field by key. Returns 0 when not found.
- static double **_extractJsonDouble** (const std::string &json, const std::string &key)

  Extracts the value of a top-level JSON number field (int or float) by key. Returns 0.0 when not found.
- static std::string **_buildMessagesArray** (const std::vector< ChatMessage > &messages)

  Serialises a vector of ChatMessage objects to a JSON array string.
- static std::string **_extractFirstArrayElement** (const std::string &json, const std::string &arrayKey)

  Extracts the raw substring of the first element of a named JSON array. Returns an empty string when not found.

Protected Member Functions

- virtual std::string _buildRequestBody (const ProviderRequest &request) const =0

  Serialises `request` to the provider's JSON wire format.
- virtual ProviderResponse _parseResponseBody (const std::string &rawBody, int httpStatus) const =0

  Deserialises `rawBody` (the full curl stdout) into a ProviderResponse.
- virtual std::string _authorizationHeader () const =0

  Returns the Authorization header line without the "header = " prefix.
- virtual std::vector< std::string > _extraRequestHeaders () const

  Returns additional HTTP headers to send with every request.

Protected Attributes

- std::string **_baseUrl**
- unsigned int **_timeoutSeconds** = 30
- std::string _apiKey

  In-memory API key.

17.390.1 Detailed Description

Abstract base class for HTTP-based AI provider clients.
Implements the common parts of AIProviderClient_if that are shared across all cloud and local provider backends:

- In-memory API key management with the same security contract as AIAssistant_if.
- Base URL and timeout configuration.
- A synchronous send() that builds a curl command, writes the API key and request body to temporary files, invokes curl via popen(), and returns the raw response body to the subclass for parsing.

17.390.1.1 Transport design

The HTTP request is executed by shelling out to the system `curl` binary. This avoids any C++ HTTP library dependency while remaining portable. Security considerations:

- The API key is written to a temporary curl config file created with mkstemp() and restricted to mode 0600. The key is never passed on the command line, keeping it out of /proc/<pid>/cmdline and shell history.
- Both the body temp file and the config temp file are unlinked immediately after the curl invocation begins (unlink-before-pclose pattern).

17.390.1.2 Subclass responsibilities

Concrete implementations must override:

- _buildRequestBody() — serialise ProviderRequest to the provider's JSON format.
- _parseResponseBody() — deserialise the raw HTTP body to ProviderResponse.
- _authorizationHeader() — return the full auth header line (e.g. "Authorization: Bearer <key>").
- _extraRequestHeaders() — return additional provider-specific headers (default: none).

17.390.1.3 curl dependency

curl must be installed and on PATH at runtime. If curl is unavailable, send() returns a ProviderResponse with success=false and a descriptive error message.

17.390.2 Member Function Documentation

17.390.2.1 _authorizationHeader()

```
virtual std::string HttpProviderClientBase::_authorizationHeader ( ) const  [protected], [pure virtual]
```

Returns the Authorization header line without the "header = " prefix.
Example return values:

- "Authorization: Bearer sk-..." (OpenAI, LocalProvider)
- "x-api-key: sk-ant-..." (Anthropic)

Called only from within send(); the value is written to a 0600 temp file and never logged.
Implemented in AnthropicProviderClientImpl, LocalProviderClientImpl, and OpenAIProviderClientImpl.

17.390.2.2 _buildRequestBody()

```
virtual std::string HttpProviderClientBase::_buildRequestBody (
            const ProviderRequest & request ) const  [protected], [pure virtual]
```

Serialises `request` to the provider's JSON wire format.
Implemented in AnthropicProviderClientImpl, LocalProviderClientImpl, and OpenAIProviderClientImpl.

17.390.2.3 _extraRequestHeaders()

```
std::vector< std::string > HttpProviderClientBase::_extraRequestHeaders ( ) const  [protected], [virtual]
```

Returns additional HTTP headers to send with every request.
Default implementation returns an empty vector. Anthropic overrides to add "anthropic-version: 2023-06-01".
Each element must be a complete header line, e.g. "anthropic-version: 2023-06-01".
Reimplemented in AnthropicProviderClientImpl, and OpenAIProviderClientImpl.

17.390.2.4 _parseResponseBody()

```
virtual ProviderResponse HttpProviderClientBase::_parseResponseBody (
            const std::string & rawBody,
            int httpStatus ) const  [protected], [pure virtual]
```

Deserialises `rawBody` (the full curl stdout) into a ProviderResponse.

Parameters

rawBody	Complete HTTP response body as received from curl.
httpStatus	HTTP status code captured from curl exit / response line, or 0 when unavailable.

Implemented in AnthropicProviderClientImpl, LocalProviderClientImpl, and OpenAIProviderClientImpl.

17.390.2.5 clearApiKey()

```
void HttpProviderClientBase::clearApiKey ( )  [override], [virtual]
```

Overwrites (best-effort) and clears the in-memory API key.
Implements AIProviderClient_if.

17.390.2.6 getBaseUrl()

```
std::string HttpProviderClientBase::getBaseUrl ( ) const  [override], [virtual]
```

Returns the currently configured base URL.
Implements AIProviderClient_if.

17.390.2.7 getTimeoutSeconds()

```
unsigned int HttpProviderClientBase::getTimeoutSeconds ( ) const  [override], [virtual]
```

Returns the configured HTTP request timeout.
Implements AIProviderClient_if.

17.390.2.8 hasApiKey()

```
bool HttpProviderClientBase::hasApiKey ( ) const  [override], [virtual]
```

Returns `true` when a non-empty API key is held.
Implements AIProviderClient_if.

17.390.2.9 isAvailable()

```
bool HttpProviderClientBase::isAvailable ( ) const  [override], [virtual]
```

Returns `true` when this client can attempt to send requests.
A client is considered available when it holds an API key (if required by the provider) and a reachable base URL.
Implements AIProviderClient_if.
Reimplemented in LocalProviderClientImpl, and OpenAIProviderClientImpl.

17.390.2.10 send()

```
ProviderResponse HttpProviderClientBase::send (
            const ProviderRequest & request )  [override], [virtual]
```

Executes the HTTP request via curl and returns the provider response.
Steps:

1. Calls _buildRequestBody() to serialise the request.
2. Writes the body JSON to a temp file.
3. Writes a curl config file with URL, headers (including auth), data reference, and timeout.
4. Invokes curl via popen(), capturing stdout.

5. Unlinks both temp files.
6. Calls _parseResponseBody() on the captured output.

Implements AIProviderClient_if.

17.390.2.11 setApiKey()

```
void HttpProviderClientBase::setApiKey (
            const std::string & apiKey )  [override], [virtual]
```

Stores the API key in memory.
Never write the key to disk or logs. Prefer loading from an environment variable via the owning AIAssistant_if rather than embedding keys in source.
Implements AIProviderClient_if.

17.390.2.12 setBaseUrl()

```
void HttpProviderClientBase::setBaseUrl (
            const std::string & url )  [override], [virtual]
```

Sets the base URL for the provider API endpoint.
Implements AIProviderClient_if.

17.390.2.13 setTimeoutSeconds()

```
void HttpProviderClientBase::setTimeoutSeconds (
            unsigned int seconds )  [override], [virtual]
```

Sets the HTTP request timeout in seconds.
Implements AIProviderClient_if.

17.390.3 Member Data Documentation

17.390.3.1 _apiKey

```
std::string HttpProviderClientBase::_apiKey  [protected]
```

In-memory API key.
Security contract (matches AIAssistant_if):

- Never written to disk.
- Never included in log or trace output.
- Not accessible via a public getter.
- Overwritten (best-effort) before clearing in clearApiKey().

The documentation for this class was generated from the following files:

- tools/AIAssistant/HttpProviderClientBase.h
- tools/AIAssistant/HttpProviderClientBase.cpp

17.391 HttpRequest Struct Reference

Lightweight representation of one parsed HTTP request.
`#include <applications/worker/http/HttpRequest.h>`

Public Member Functions

- std::string header (const std::string &name) const

  Returns a header value using a case-insensitive lookup.

Public Attributes

- std::string **method**

  HTTP method token as received from the request line.
- std::string **path**

  Request target path used by the API router.
- std::string **body**

  Raw body payload passed to JSON parsers and handlers.
- std::unordered_map< std::string, std::string > **headers**

  Lowercase header map used for case-insensitive lookups.

17.391.1 Detailed Description

Lightweight representation of one parsed HTTP request.
The worker application uses a small transport surface, so the request keeps only the pieces needed by the router: method, path, raw body and normalized header lookup.

17.391.2 Member Function Documentation

17.391.2.1 header()

```
std::string HttpRequest::header (
            const std::string & name ) const  [inline]
```

Returns a header value using a case-insensitive lookup.

Parameters

name	Header name to search.

Returns

Header value when present, or an empty string otherwise.

The documentation for this struct was generated from the following file:

- applications/worker/http/HttpRequest.h

17.392 HttpResponse Struct Reference

Minimal HTTP response payload produced by the web API router.
`#include <applications/worker/http/HttpResponse.h>`

Public Attributes

- int **status** = 200

  HTTP status code returned to the client.
- std::string **contentType** = "application/json"

  MIME type advertised in the response.
- std::string **body**

  Raw response body, usually JSON.
- std::unordered_map< std::string, std::string > **headers**

  Arbitrary response headers written by the router or handlers.

17.392.1 Detailed Description

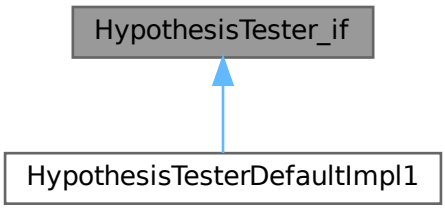
Minimal HTTP response payload produced by the web API router.

The response mirrors the small transport model used by the embedded server: status, content type, body, and a simple header map.
The documentation for this struct was generated from the following file:

- applications/worker/http/HttpResponse.h

17.393 HypothesisTester_if Class Reference

Interface for classical parametric inference.
`#include <tools/Statistics/HypothesisTester_if.h>`
Inheritance diagram for HypothesisTester_if:



Classes

- class ConfidenceInterval

  Confidence interval [inferior, superior] and its half-width e0.
- class TestResult

  Result of a parametric hypothesis test.

Public Types

- enum H1Comparition { **DIFFERENT** = 1 , **LESS_THAN** = 2 , **GREATER_THAN** = 3 }

  Alternative-hypothesis comparison mode. DIFFERENT: two-sided; LESS_THAN: left-tailed; GREATER_THAN: right-tailed.

Public Member Functions

- virtual HypothesisTester_if::ConfidenceInterval **averageConfidenceInterval** (double avg, double stddev, unsigned int n, double confidenceLevel)=0

- virtual HypothesisTester_if::TestResult **testVariance** (std::string firstSampleDataFilename, std::string secondSampleDataFilename, double confidenceLevel, HypothesisTester_if::H1Comparition comp)=0

17.393.1 Detailed Description

Interface for classical parametric inference.
Purpose:

- Provide confidence intervals and hypothesis tests from parameters or dataset files.

Mathematical meaning:

- Contract follows classical statistical inference for one-population and two-population analyses.

Confidence level contract:

- All confidenceLevel parameters are expected to be probabilities in [0, 1].

The documentation for this class was generated from the following file:

- tools/Statistics/HypothesisTester_if.h

17.394 HypothesisTesterDefaultImpl1 Class Reference

Current default implementation of HypothesisTester_if.
`#include <tools/Statistics/HypothesisTesterDefaultImpl1.h>`

Additional Inherited Members

Public Types inherited from HypothesisTester_if

- enum H1Comparition { **DIFFERENT** = 1 , **LESS_THAN** = 2 , **GREATER_THAN** = 3 }

  Alternative-hypothesis comparison mode. DIFFERENT: two-sided; LESS_THAN: left-tailed; GREATER_THAN: right-tailed.

17.394.1 Detailed Description

Current default implementation of HypothesisTester_if.
Architectural role:

- Best available legacy implementation in the tools package.

Implementation status:

- Partially consolidated. One-population methods are mostly available; two-population routines still require theoretical and implementation alignment.

Planned evolution:

- Continue converging to a fully consistent implementation based on formal classical hypothesis-testing theory.

17.394.2 Member Function Documentation

17.394.2.1 averageConfidenceInterval() [1/2]

```
HypothesisTester_if::ConfidenceInterval HypothesisTesterDefaultImpl1::averageConfidence↩
Interval (
            double avg,
```

```
            double stddev,
            unsigned int n,
            double confidenceLevel )  [override], [virtual]
```

Implements HypothesisTester_if.

17.394.2.2 averageConfidenceInterval() [2/2]

```
HypothesisTester_if::ConfidenceInterval HypothesisTesterDefaultImpl1::averageConfidence↩
Interval (

17.411 IssueReportDraft Struct Reference

User-authored issue report collected by the GUI form before transport.
`#include <applications/gui/genesys/services/IssueReportRelayService.h>`

Public Attributes

- QString **categoryKey**
- QString **categoryLabel**
- QString **title**
- QString **summary**
- QString **reproductionSteps**
- QString **expectedBehavior**
- QString **observedBehavior**
- QString **additionalContext**
- QString **contactEmail**
- bool **includeScreenshot** = false
- bool **includeLogTail** = true
- bool **includeModelText** = false

17.411.1 Detailed Description

User-authored issue report collected by the GUI form before transport.
The documentation for this struct was generated from the following file:

- applications/gui/genesys/services/IssueReportRelayService.h

17.412 IssueReportRelayService Class Reference

HTTPS client service that sends issue reports to a secure relay endpoint.
`#include <applications/gui/genesys/services/IssueReportRelayService.h>`

Static Public Member Functions

- static QString **configuredEndpoint** ()
- static QString **optionalClientKey** ()
- static int **requestTimeoutMs** ()
- static bool **isEndpointConfigured** (QString *reason=nullptr)
- static IssueReportSubmissionResult **submit** (const IssueReportDraft &draft, const IssueReportRuntimeContext &runtimeContext)

17.412.1 Detailed Description

HTTPS client service that sends issue reports to a secure relay endpoint.
Responsibilities:

- validate relay configuration from environment;
- serialize the GUI report and runtime diagnostics into JSON;
- submit the payload via HTTPS and normalize the relay response.

Boundaries:

- it does not talk directly to GitHub with a secret embedded in the client;
- it does not own UI widgets or present dialogs;
- it assumes an external relay exists and enforces server-side policy.

The documentation for this class was generated from the following files:

- applications/gui/genesys/services/IssueReportRelayService.h
- applications/gui/genesys/services/IssueReportRelayService.cpp

17.413 IssueReportRuntimeContext Struct Reference

Runtime diagnostics captured by the GUI after the user approves submission.
`#include <applications/gui/genesys/services/IssueReportRelayService.h>`

Public Attributes

- QString **applicationName**
- QString **applicationVersion**
- QString **qtVersion**
- QString **operatingSystem**
- QString **currentModelName**
- QString **currentModelSimulanguage**
- QString **consoleTail**
- QString **simulationTail**
- QString **reportsTail**
- QString **processLogTail**
- QByteArray **screenshotPngBase64**

17.413.1 Detailed Description

Runtime diagnostics captured by the GUI after the user approves submission.
The documentation for this struct was generated from the following file:

- applications/gui/genesys/services/IssueReportRelayService.h

17.414 IssueReportSubmissionResult Struct Reference

Relay submission outcome returned to the controller layer.
`#include <applications/gui/genesys/services/IssueReportRelayService.h>`

Public Attributes

- bool **success** = false
- int **httpStatus** = 0
- int **issueNumber** = 0
- QString **issueUrl**
- QString **errorMessage**
- QString **responseBody**

17.414.1 Detailed Description

Relay submission outcome returned to the controller layer.
The documentation for this struct was generated from the following file:

- applications/gui/genesys/services/IssueReportRelayService.h

17.415 genesys::launcher::IUpdateUi Class Reference

Inheritance diagram for genesys::launcher::IUpdateUi:

- virtual void **finishDownload** ()=0
- virtual void **showError** (const QString &message)=0
- virtual void **showInfo** (const QString &message)=0

The documentation for this class was generated from the following file:

- applications/launcher/UpdateDialog.h

17.416 Json Struct Reference

Public Types

- enum **Kind** {
  null , **boolean** , **number** , **string** ,
  array , **object** }

Public Attributes

- enum Json::Kind **kind**
- double **value**
- std::string **text**
- std::vector< std::unique_ptr< Json > > sequence
- std::unordered_map< std::string, std::unique_ptr< Json > > fields

17.416.1 Member Data Documentation

17.416.1.1 fields

```
std::unordered_map<std::string, std::unique_ptr<Json> > Json::fields
```

Initial value:

```
{
    }
```

17.416.1.2 sequence

```
std::vector<std::unique_ptr<Json> > Json::sequence
```

Initial value:

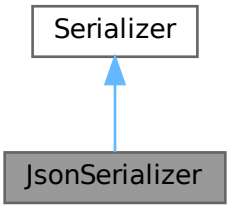
```
{
    }
```

The documentation for this struct was generated from the following file:

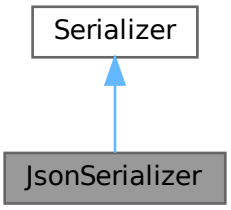
- kernel/simulator/persistence/JsonSerializer.cpp

17.417 JsonSerializer Class Reference

Inheritance diagram for JsonSerializer:



Collaboration diagram for JsonSerializer:



Public Member Functions

- **JsonSerializer** (Model ∗model)
- PersistenceRecord ∗ newPersistenceRecord () override

  Creates an empty persistence record.
- bool dump (std::ostream &output) override

  Writes formatted contents to a given output stream.
- bool load (std::istream &input) override

  Attempts to load contents from a given input stream.
- bool get (const std::string &name, PersistenceRecord ∗entry) override

  Tries to fetch an entry with the given label as a key.

- bool put (const std::string name, const std::string type, const Util::identification id, PersistenceRecord *fields) override

  Upserts an entry into this structure.
- int for_each (std::function< int(const std::string &) > delegate) override

  Iterates over this structure's entries, ordered by ID.

17.417.1 Member Function Documentation

17.417.1.1 dump()

```
bool JsonSerializer::dump (
            std::ostream & output )  [override], [virtual]
```

Writes formatted contents to a given output stream.

Parameters

output	output stream to write to.

Returns

whether the current state of this structure's contents was deemed valid for serialization.

Implements Serializer.

17.417.1.2 for_each()

```
int JsonSerializer::for_each (
            std::function< int(const std::string &) > delegate )  [override], [virtual]
```

Iterates over this structure's entries, ordered by ID.

Parameters

delegate	delegate which is applied to every entry-identifying key, until it returns a non-zero value.

Returns

either zero, or the first non-zero value returned by the delegate.

Implements Serializer.

17.417.1.3 get()

```
bool JsonSerializer::get (
            const std::string & name,
            PersistenceRecord * entry )  [override], [virtual]
```

Tries to fetch an entry with the given label as a key.

Parameters

name	a label which uniquely identifies an entry.
entry	(out-param) a pointer to a caller-owned entry, which is filled on success.

Returns

whether the entry was found and the out-param was actually written to.

Implements Serializer.

17.417.1.4 load()

```
bool JsonSerializer::load (
            std::istream & input )  [override], [virtual]
```

Attempts to load contents from a given input stream.

Returns

whether the input was well-formatted and loading was successful.

Implements Serializer.

17.417.1.5 newPersistenceRecord()

```
PersistenceRecord * JsonSerializer::newPersistenceRecord ( )  [override], [virtual]
```

Creates an empty persistence record.
Although the returned record can be freed normally with `delete`, care must be taken to only use records which come from a implementation, when configuring that implementation's contents.
Implements Serializer.

17.417.1.6 put()

```
bool JsonSerializer::put (
            const std::string name,
            const std::string type,
            const Util::identification id,
            PersistenceRecord * fields )  [override], [virtual]
```

Upserts an entry into this structure.

Parameters

name	a label which uniquely identifies the entry.
type	a type name.
id	a component/datadef ID number.
fields	a persistence record for the entry, whose contents will be copied if valid.

Returns

whether the entry was valid and was actually copied into this structure.

Implements Serializer.
The documentation for this class was generated from the following files:

- kernel/simulator/persistence/JsonSerializer.h
- kernel/simulator/persistence/JsonSerializer.cpp

17.418 KernelAccessorProbe Struct Reference

Public Member Functions

- std::string **getName** () const
- void **setName** (std::string newName)

Public Attributes

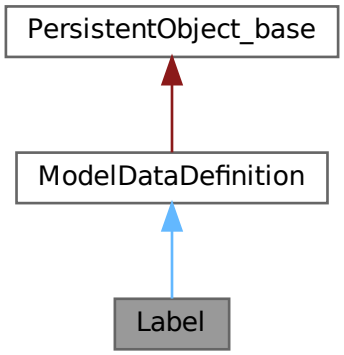
- std::string **name** = "alpha"

The documentation for this struct was generated from the following file:

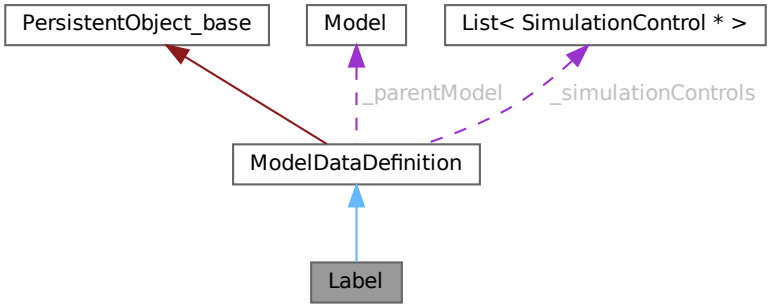
- tests/unit/test_simulator_support.cpp

17.419 Label Class Reference

Inheritance diagram for Label:



Collaboration diagram for Label:



Public Member Functions

- **Label** (Model *model, std::string name="")
- virtual std::string show () override

  Returns a textual representation of this data definition.
- void **setLabel** (std::string _label)
- std::string **getLabel** () const
- void **setEnterIntoLabelComponent** (ModelComponent *enteringLabelComponent)
- ModelComponent * **getEnterIntoLabelComponent** () const
- void **sendEntityToLabelComponent** (Entity *entity, double timeDelay)

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.

- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static ModelDataDefinition * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static PluginInformation * **GetPluginInformation** ()
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  must be overriden by derived classes
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes

Protected Member Functions inherited from ModelDataDefinition

```
bool Label::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.419.1.3 _saveInstance()

```
void Label::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.

17.419.1.4 show()

```
std::string Label::show ( )  [override], [virtual]
```

Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from ModelDataDefinition.

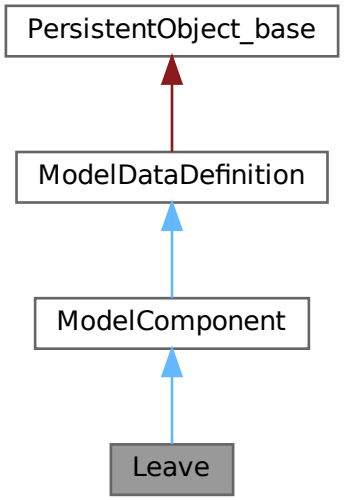
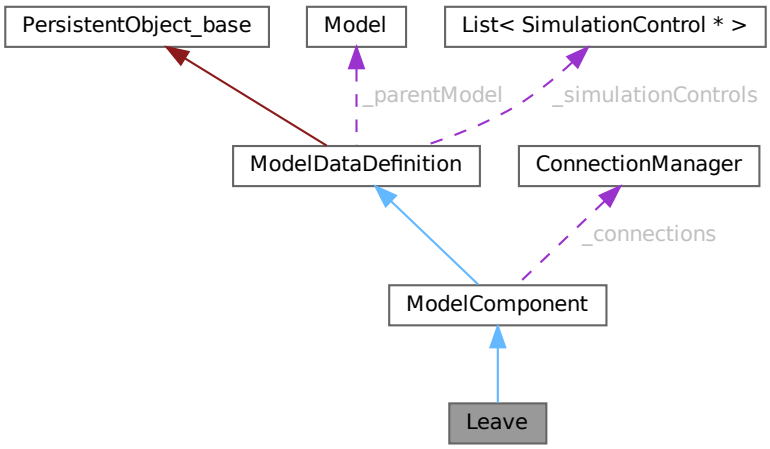
17.426 Leave Class Reference

```
#include <plugins/components/MaterialHandling/Leave.h>
```

Inheritance diagram for Leave:



Collaboration diagram for Leave:



Public Member Functions

- **Leave** (Model ∗model, std::string name="")
- virtual std::string show () override

  virtual public methods
- void **setStation** (Station ∗_station)
- void **setStationName** (std::string stationName)
- Station ∗ **getStation** () const

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

Creates internal and attached data required by this instance.

- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual void _createInternalStatisticReporters () override
- virtual void _createEditableDataDefinitions () override
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual ParserChangesInformation * _getParserChangesInformation ()
- virtual void _initBetweenReplications ()
- virtual void _addSimulationControl (SimulationControl *control)
- virtual void _createInternalAndAttachedData ()
- virtual void _createAttachedAttributes ()
- virtual void _createNonEditableDataDefinitions ()
- void **_templateCreateInternalStatisticReporters** ()
- void **_templateCreateAttachedAttributes** ()
- void **_templateCreateNonEditableDataDefinitions** ()
- void **_templateCreateEditableDataDefinitions** ()
- void **_internaStatisticReportersClear** ()

  legacy helper methods used by the granular create hooks*
- void **_internalDataClear** ()
- void **_internalDataInsert** (const std::string &key, ModelDataDefinition *child)
- void **_internalDataRemove** (const std::string &key)
- void **_attachedDataClear** ()
- void **_attachedDataInsert** (const std::string &key, ModelDataDefinition *data)
- void **_attachedDataRemove** (const std::string &key)
- void **_attachedAttributesInsert** (const std::vector< std::string > &neededNames)
- void **_statisticReporterInsert** (const std::string &key, ModelDataDefinition *data)
- void **_statisticReporterRemove** (const std::string &key)
- void **_statisticReportersClear** ()
- void **_mandatoryAttachedAttributeInsert** (const std::string &key, ModelDataDefinition *data)
- void **_mandatoryAttachedAttributeRemove** (const std::string &key)
- void **_mandatoryAttachedAttributesClear** ()
- void **_mandatoryEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_mandatoryEditableDataDefinitionRemove** (const std::string &key)
- void **_mandatoryEditableDataDefinitionsClear** ()
- void **_optionalEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_optionalEditableDataDefinitionRemove** (const std::string &key)
- void **_optionalEditableDataDefinitionsClear** ()
- void **_mandatoryNonEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_mandatoryNonEditableDataDefinitionRemove** (const std::string &key)
- void **_mandatoryNonEditableDataDefinitionsClear** ()

- void **_optionalNonEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_optionalNonEditableDataDefinitionRemove** (const std::string &key)
- void **_optionalNonEditableDataDefinitionsClear** ()
- void **_checkCreateAttachedReferencedDataDefinition** (const std::string &expression)

  method to be called to insert attached dataelements that are referenced by string expressions (detected by the parser), to avoid orphaned data definitions
- void **trace** (const std::string &text, TraceManager::Level level=TraceManager::Level::L8_detailed)

  not just an easy access to trace manager, but wrappers to check if specific trace level applies
- void **traceError** (const std::string &text, const std::exception &e)
- void **traceError** (const std::string &text, TraceManager::Level level=TraceManager::Level::L1_errorFatal)
- void **traceReport** (const std::string &text, TraceManager::Level level=TraceManager::Level::L2_results)
- void **traceSimulation** (void *thisobject, double time, Entity *entity, ModelComponent *component, const std::string &text, TraceManager::Level level=TraceManager::Level::L8_detailed)
- void traceSimulation (void *thisobject, const std::string &text, TraceManager::Level level=TraceManager::↩ Level::L8_detailed)

  Traces text to the simulation output.
- void **traceSimulation** (void *thisobject, TraceManager::Level level, const std::string &text)

Additional Inherited Members

Protected Attributes inherited from ModelComponent

- ConnectionManager * _connections = new ConnectionManager()

  virtual protected methods that could be overriden by derived classes, if needed

Protected Attributes inherited from ModelDataDefinition

- List< SimulationControl * > * **_simulationControls** = new List<SimulationControl*>()
- TraceManager::Level **_traceLevelSpecific**
- bool **_traceLevelSpecificEnabled** = false

17.426.1 Detailed Description

Leave module DESCRIPTION The Leave module is used to transfer an entity to a station or module. An entity may be transferred in two ways. It can be transferred to a module that defines a station by referencing the station and routing, conveying, or transporting to that station, or a graphical connection can be used to transfer an entity to another module. When an entity arrives at a Leave module, it may wait to obtain a transfer device (resource, transporter, or conveyor). When the transfer device has been obtained, the entity may experience a loading delay. Finally, the entity is transferred from this module to a destination module or station. TYPICAL USES The end of a part's production in a series of parallel processes where the part needs a forklift to be transferred to shipping PROMPTS Prompt Description Name Unique name of the module that will be displayed in the flowchart. Allocation Type of category to which the entity's incurred delay time and cost will be added. Delay Specifies a load time incurred after getting a transfer device. Units Time units used for the delay time. Transfer Out Determines whether a resource (Seize Resource), transporter (Request Transporter), or conveyor (Access Conveyor) is required prior to transferring the entity out of this module. Priority Indicates the priority of the module when either seizing a resource or requesting a transporter when there are entities waiting for that resource/transporter from other modules. This field is not visible when the Transfer Type is None or Access Conveyor. Transporter Name Name of the transporter to request. Queue Type Type of queue, either a single Queue, queue Set, Internal queue, Attribute, or Expression. Queue Name Name of the individual queue. Queue Set Name Name of the queue set. Set Index Defines the index into the queue set. Note that this is the index into the set and not the name of the queue in the set. Queue

Attribute Name The attribute name that will be evaluated to indicate which queue is to be used. Queue Expression The expression that will be evaluated to indicate which queue is to be used. Selection Rule Method of selecting among available transporters in a set. Cyclical will cycle through available members. Random will randomly select a member. Preferred Order will always select the first available member. Specific Member requires an input attribute value to specify which member of the set (previously saved in the Save Attribute field). Largest Distance selects the transporter farthest away, and Smallest Distance selects the closest transporter. Save Attribute Attribute name used to store the index number into the set of the member that is chosen. This attribute can later be referenced with the Specific Member selection rule. Active when Transfer Out is Request Transporter. Index Set Attribute name whose value identifies the index number into the set of the member requested. The entity must have a value for the attribute before utilizing this option. Resource Type Type of resource for seizing, either specifying a particular Resource, selecting from a pool of resources (that is, a resource Set), Attribute, or Expression. Resource Name Name of the resource to seize. Conveyor Name Name of the conveyor to access.

17.426.2 of Cells Number of contiguous cells the entity requires.

Connect Type Determines if the entity is to Route, Convey, or Transport to another station or Connect to another module. Move Time Time to route from this module to the destination station. Units Time units used for the move time. Station Type The entity's destination station type either an individual Station, a station based on an Attribute or Expression value, or By Sequence. Station Name Name of the individual destination station. Attribute Name The attribute name that will be evaluated to indicate the station. Expression The expression that will be evaluated to indicate the station.

17.426.3 Member Function Documentation

17.426.3.1 _check()

```
bool Leave::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.426.3.2 _createEditableDataDefinitions()

```
void Leave::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.426.3.3 _createInternalStatisticReporters()

```
void Leave::_createInternalStatisticReporters ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.426.3.4 _loadInstance()

```
bool Leave::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.426.3.5 _onDispatchEvent()

```
void Leave::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.426.3.6 _saveInstance()

```
void Leave::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.426.3.7 show()

```
std::string Leave::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

- plugins/components/MaterialHandling/Leave.h
- plugins/components/MaterialHandling/Leave.cpp

17.427 LicenceManager Class Reference

```
#include <kernel/simulator/LicenceManager.h>
```

Public Member Functions

- **LicenceManager** (Simulator *simulator)
- const std::string **showLicence** () const
- const std::string **showLimits** () const
- const std::string **showActivationCode** () const
- bool **lookforActivationCode** ()
- bool **insertActivationCode** ()
- void **removeActivationCode** ()
- unsigned int **getModelComponentsLimit** ()
- unsigned int **getModelDatasLimit** ()
- unsigned int **getEntityLimit** ()
- unsigned int **getHostsLimit** ()
- unsigned int **getThreadsLimit** ()

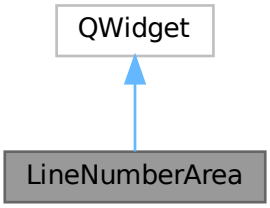
17.427.1 Detailed Description

LicenceManager just prints a licence agreement and checks for some resource limits.
The documentation for this class was generated from the following files:

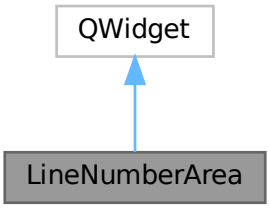
- kernel/simulator/LicenceManager.h
- kernel/simulator/LicenceManager.cpp

17.428 LineNumberArea Class Reference

Inheritance diagram for LineNumberArea:



Collaboration diagram for LineNumberArea:



Public Member Functions

- **LineNumberArea** (CodeEditor *editor)
- QSize **sizeHint** () const override

Protected Member Functions

- void **paintEvent** (QPaintEvent *event) override

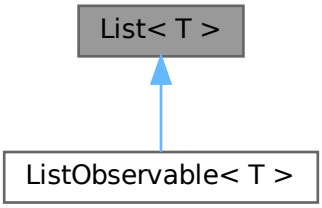
The documentation for this class was generated from the following file:

- applications/gui/genesys/codeeditor/LineNumberArea.h

17.429 List< T > Class Template Reference

Lightweight wrapper around `std::list` with convenience helpers used by the kernel.
`#include <kernel/util/List.h>`

Inheritance diagram for List< T >:



Public Types

- using **CompFunct** = std::function< bool(const T, const T) >

Public Member Functions

- **List** ()

  Creates an empty list and positions the internal iterator at the beginning.
- **List** (const List< T > &origin)

  Creates a copy of the source list.
- List< T > & **operator=** (const List< T > &origin)
- unsigned int **size** ()

  Returns the number of stored elements.
- bool **empty** ()

  Indicates whether the list is empty.
- void **clear** ()

  Removes all elements from the list.
- void **pop_front** ()

  Removes the first element from the list.
- template<class Compare >
  void **sort** (Compare comp)

  Sorts elements using the provided comparator.
- std::list< T > * **list** () const

  Returns direct access to the encapsulated `std::list` structure.
- T **create** ()

  Creates a new default element of type `T`.
- template<typename U >
  T **create** (U arg)

  Creates a new `T` element using a construction argument.
- std::string **show** ()

  Generates a textual representation of elements for debugging.
- std::list< T >::iterator **find** (T element)

  Searches for an element and returns an iterator to it (or `end()`).
- void **insert** (T element)

  Inserts an element preserving the current ordering policy.
- void **remove** (T element)

  Removes all occurrences of the provided element.

- void **setAtRank** (unsigned int rank, T element)

  Replaces (or appends) an element at a specific rank.
- T **getAtRank** (unsigned int rank)

  Returns the element at the provided rank.
- T **next** ()

  Advances the internal iterator and returns the next element.
- T **front** ()

  Moves to the beginning and returns the first element.
- T **last** ()

  Moves to the end and returns the last element.
- T **previous** ()

  Moves the internal iterator backward and returns the previous element.
- T **current** ()

  Returns the element at the current internal iterator position.
- void **setSortFunc** (CompFunct _sortFunc)

  Sets the comparison function used for ordered insertions.

Protected Attributes

- std::list< T > * **_list**
- CompFunct _sortFunc
- std::list< T >::iterator **_it**

  Default function: insert at the end of the list.

17.429.1 Detailed Description

template<typename T>
class List< T >

Lightweight wrapper around `std::list` with convenience helpers used by the kernel.
The class centralizes insertion/removal, rank-based access and iterator-like navigation patterns heavily used in simulator internals and plugin infrastructure.

17.429.2 Member Data Documentation

17.429.2.1 _sortFunc

```
template<typename T >
CompFunct List< T >::_sortFunc  [protected]
```

Initial value:

```
{[](const T, const T) {
            return false;
        }}
```

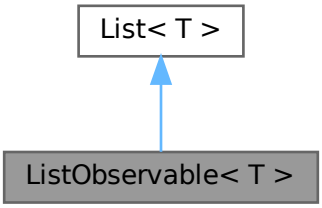
The documentation for this class was generated from the following files:

- applications/gui/genesys/services/GraphicalModelBuilder.h
- kernel/util/List.h

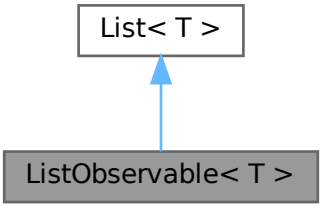
17.430 ListObservable< T > Class Template Reference

Observable-oriented list variant used by kernel structures.
`#include <kernel/util/ListObservable.h>`

Inheritance diagram for ListObservable< T >:



Collaboration diagram for ListObservable< T >:



Public Types

- using **CompFunct** = std::function< bool(const T, const T) >

Public Types inherited from List< T >

- using **CompFunct** = std::function< bool(const T, const T) >

Public Member Functions

- **ListObservable** ()

  Initializes an empty observable list.
- void **clear** ()

  Removes all elements from the observable list.
- void **pop_front** ()

  Removes the first element from the observable list.
- void **insert** (T element)

  Inserts an element respecting the configured ordering.
- void **remove** (T element)

  Removes an element from the observable list.
- void **setAtRank** (unsigned int rank, T element)

  Sets the element at a specific list index.

Public Member Functions inherited from List< T >

- **List** ()

  Creates an empty list and positions the internal iterator at the beginning.
- **List** (const List< T > &origin)

  Creates a copy of the source list.
- List< T > & **operator=** (const List< T > &origin)
- unsigned int **size** ()

  Returns the number of stored elements.
- bool **empty** ()

  Indicates whether the list is empty.
- void **clear** ()

  Removes all elements from the list.
- void **pop_front** ()

  Removes the first element from the list.
- template<class Compare >
  void **sort** (Compare comp)

  Sorts elements using the provided comparator.
- std::list< T > * **list** () const

  Returns direct access to the encapsulated `std::list` structure.
- T **create** ()

  Creates a new default element of type `T`.
- template<typename U >
  T **create** (U arg)

  Creates a new `T` element using a construction argument.
- std::string **show** ()

  Generates a textual representation of elements for debugging.
- std::list< T >::iterator **find** (T element)

  Searches for an element and returns an iterator to it (or `end()`).
- void **insert** (T element)

  Inserts an element preserving the current ordering policy.
- void **remove** (T element)

  Removes all occurrences of the provided element.
- void **setAtRank** (unsigned int rank, T element)

  Replaces (or appends) an element at a specific rank.
- T **getAtRank** (unsigned int rank)

  Returns the element at the provided rank.
- T **next** ()

  Advances the internal iterator and returns the next element.
- T **front** ()

  Moves to the beginning and returns the first element.
- T **last** ()

  Moves to the end and returns the last element.
- T **previous** ()

  Moves the internal iterator backward and returns the previous element.
- T **current** ()

  Returns the element at the current internal iterator position.
- void **setSortFunc** (CompFunct _sortFunc)

  Sets the comparison function used for ordered insertions.

Additional Inherited Members

Protected Attributes inherited from List< T >

- std::list< T > * **_list**
- CompFunct _sortFunc
- std::list< T >::iterator **_it**

  Default function: insert at the end of the list.

17.430.1 Detailed Description

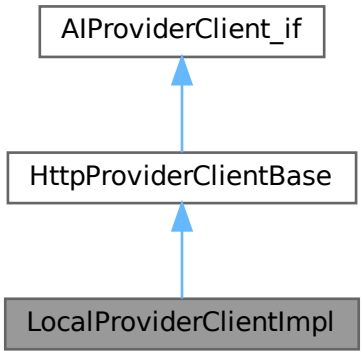
template<typename T>
class ListObservable< T >

Observable-oriented list variant used by kernel structures.
This template specializes `List` behavior for contexts where list mutations are relevant to external observers/managers, while preserving familiar list helpers.
The documentation for this class was generated from the following file:

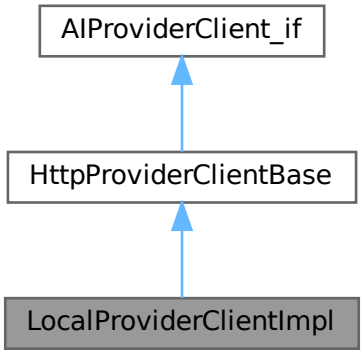
- kernel/util/ListObservable.h

17.431 LocalProviderClientImpl Class Reference

AI provider client for local model servers (Ollama, LM Studio, etc.).
`#include <tools/AIAssistant/LocalProviderClientImpl.h>`
Inheritance diagram for LocalProviderClientImpl:



Collaboration diagram for LocalProviderClientImpl:



Public Member Functions

- **LocalProviderClientImpl** ()

  Constructs the client targeting the default Ollama endpoint.
- std::string getProviderName () const override

  Returns a human-readable provider name (e.g. "OpenAI", "Anthropic").
- bool isAvailable () const override

  Returns `true` when a base URL is configured.

Public Member Functions inherited from HttpProviderClientBase

- **HttpProviderClientBase** (const HttpProviderClientBase &)=delete
- HttpProviderClientBase & **operator=** (const HttpProviderClientBase &)=delete
- void setBaseUrl (const std::string &url) override

  Sets the base URL for the provider API endpoint.
- std::string getBaseUrl () const override

  Returns the currently configured base URL.
- void setTimeoutSeconds (unsigned int seconds) override

  Sets the HTTP request timeout in seconds.
- unsigned int getTimeoutSeconds () const override

  Returns the configured HTTP request timeout.
- void setApiKey (const std::string &apiKey) override

  Stores the API key in memory.
- void clearApiKey () override

  Overwrites (best-effort) and clears the in-memory API key.
- bool hasApiKey () const override

  Returns `true` when a non-empty API key is held.
- ProviderResponse send (const ProviderRequest &request) override

  Executes the HTTP request via curl and returns the provider response.

Protected Member Functions

- std::string _buildRequestBody (const ProviderRequest &request) const override

  Serialises `request` to the provider's JSON wire format.
- ProviderResponse _parseResponseBody (const std::string &rawBody, int httpStatus) const override

  Deserialises `rawBody` (the full curl stdout) into a ProviderResponse.
- std::string _authorizationHeader () const override

  Returns the Authorization header when an API key is set, empty otherwise.

Protected Member Functions inherited from HttpProviderClientBase

- virtual std::vector< std::string > _extraRequestHeaders () const

  Returns additional HTTP headers to send with every request.

Additional Inherited Members

Static Public Member Functions inherited from HttpProviderClientBase

- static std::string **_escapeJsonString** (const std::string &s)

  Escapes a plain string for safe embedding inside a JSON string value.
- static std::string **_extractJsonString** (const std::string &json, const std::string &key)

  Extracts the value of a top-level JSON string field by key. Returns an empty string when not found or value is not a quoted string.
- static int **_extractJsonInt** (const std::string &json, const std::string &key)

  Extracts the value of a top-level JSON integer field by key. Returns 0 when not found.
- static double **_extractJsonDouble** (const std::string &json, const std::string &key)

  Extracts the value of a top-level JSON number field (int or float) by key. Returns 0.0 when not found.
- static std::string **_buildMessagesArray** (const std::vector< ChatMessage > &messages)

  Serialises a vector of ChatMessage objects to a JSON array string.
- static std::string **_extractFirstArrayElement** (const std::string &json, const std::string &arrayKey)

  Extracts the raw substring of the first element of a named JSON array. Returns an empty string when not found.

Protected Attributes inherited from HttpProviderClientBase

- std::string **_baseUrl**
- unsigned int **_timeoutSeconds** = 30
- std::string _apiKey

  In-memory API key.

17.431.1 Detailed Description

AI provider client for local model servers (Ollama, LM Studio, etc.).
Targets any OpenAI-compatible chat completions endpoint reachable locally. Default base URL: `http://localhost:11434/v1/chat/completions` (Ollama default).
Differences from OpenAIProviderClientImpl:

- No API key is required; isAvailable() returns true when the base URL is set.
- When a non-empty API key IS set (some local servers require a token), it is sent as `Authorization: Bearer <key>`. When no key is set, the Authorization header is omitted.
- Extended reasoning (highReasoningMode) adds `"stream": false` only; no reasoning_effort parameter (not supported by most local servers).
- The JSON request/response format otherwise mirrors OpenAI chat completions.

17.431.1.1 Tested server compatibility

- Ollama (≥0.1.29): set the base URL to `http://localhost:11434/v1/chat/completions`.
- LM Studio local server: set base URL to `http://localhost:1234/v1/chat/completions`.
- llama.cpp server: set base URL to `http://localhost:8080/v1/chat/completions`.

17.431.2 Member Function Documentation

17.431.2.1 _authorizationHeader()

```
std::string LocalProviderClientImpl::_authorizationHeader ( ) const  [override], [protected],
[virtual]
```

Returns the Authorization header when an API key is set, empty otherwise.
Implements HttpProviderClientBase.

17.431.2.2 _buildRequestBody()

```
std::string LocalProviderClientImpl::_buildRequestBody (
            const ProviderRequest & request ) const  [override], [protected], [virtual]
```

Serialises `request` to the provider's JSON wire format.
Implements HttpProviderClientBase.

17.431.2.3 _parseResponseBody()

```
ProviderResponse LocalProviderClientImpl::_parseResponseBody (
            const std::string & rawBody,
            int httpStatus ) const  [override], [protected], [virtual]
```

Deserialises `rawBody` (the full curl stdout) into a ProviderResponse.

Parameters

rawBody	Complete HTTP response body as received from curl.
httpStatus	HTTP status code captured from curl exit / response line, or 0 when unavailable.

Implements HttpProviderClientBase.

17.431.2.4 getProviderName()

```
std::string LocalProviderClientImpl::getProviderName ( ) const  [override], [virtual]
```

Returns a human-readable provider name (e.g. "OpenAI", "Anthropic").
Implements AIProviderClient_if.

17.431.2.5 isAvailable()

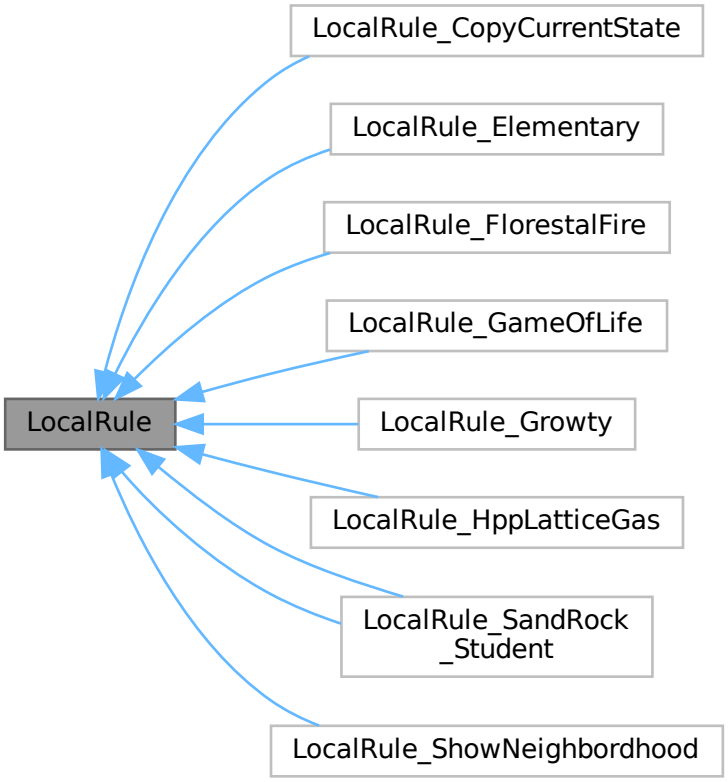
```
bool LocalProviderClientImpl::isAvailable ( ) const  [override], [virtual]
```

Returns `true` when a base URL is configured.
Unlike cloud providers, a local server does not require an API key.
Reimplemented from HttpProviderClientBase.
The documentation for this class was generated from the following files:

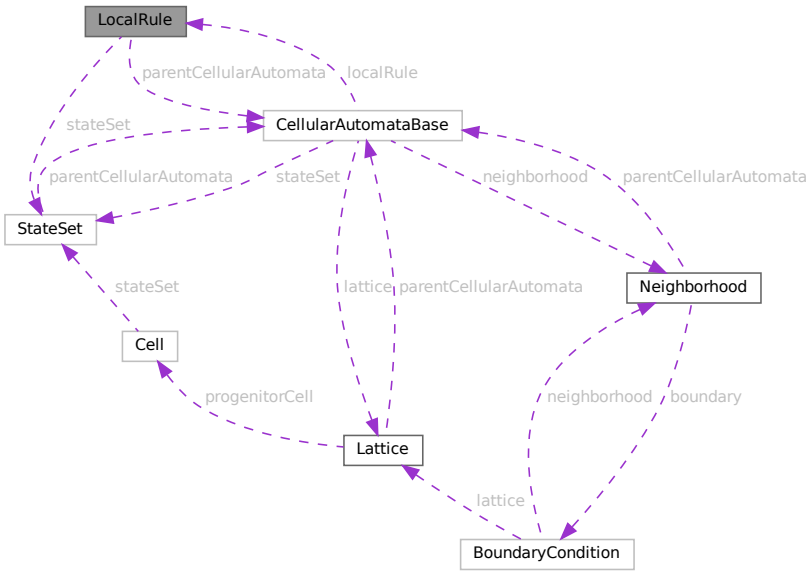
- tools/AIAssistant/LocalProviderClientImpl.h
- tools/AIAssistant/LocalProviderClientImpl.cpp

17.432 LocalRule Class Reference

Inheritance diagram for LocalRule:



Collaboration diagram for LocalRule:



Public Member Functions

- **LocalRule** (CellularAutomataBase ∗parentCellularAutomata, StateSet ∗stateSet=nullptr)
- **LocalRule** (const LocalRule &orig)
- virtual void applyRule (Cell ∗cell)=0

  Pure virtual method that has to be overiden by derived class, responsable for applying the local rule to a cell.
- void **setStateSet** (StateSet ∗stateSet)

Protected Attributes

- CellularAutomataBase ∗ **parentCellularAutomata**
- StateSet ∗ **stateSet**

17.432.1 Member Function Documentation

17.432.1.1 applyRule()

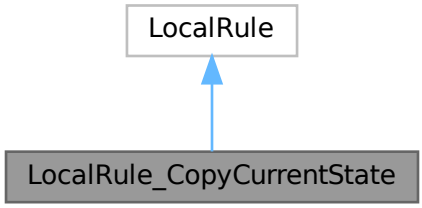
```
virtual void LocalRule::applyRule (
            Cell * cell )  [pure virtual]
```

Pure virtual method that has to be overiden by derived class, responsable for applying the local rule to a cell.
Implemented in LocalRule_ShowNeighbordhood, LocalRule_CopyCurrentState, LocalRule_Elementary, LocalRule_FlorestalFire, LocalRule_GameOfLife, LocalRule_Growty, LocalRule_HppLatticeGas, LocalRule_SandRock_Student, and LocalRule_SandRock_Student.
The documentation for this class was generated from the following file:

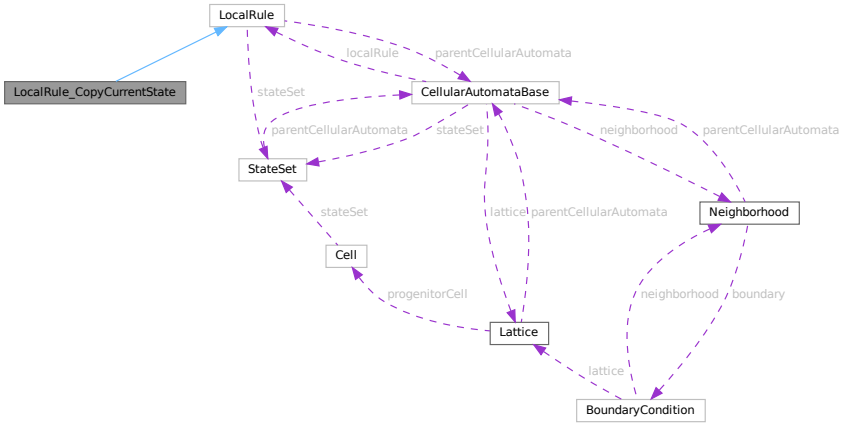
- plugins/components/ModalModel/CellularAutomata/LocalRule.h

17.433 LocalRule_CopyCurrentState Class Reference

Inheritance diagram for LocalRule_CopyCurrentState:



Collaboration diagram for LocalRule_CopyCurrentState:



Public Member Functions

- **LocalRule_CopyCurrentState** (CellularAutomataBase ∗parentCellularAutomata)
- void applyRule (Cell ∗cell) override

  Pure virtual method that has to be overiden by derived class, responsable for applying the local rule to a cell.

Public Member Functions inherited from LocalRule

- **LocalRule** (CellularAutomataBase ∗parentCellularAutomata, StateSet ∗stateSet=nullptr)
- **LocalRule** (const LocalRule &orig)
- void **setStateSet** (StateSet ∗stateSet)

Additional Inherited Members

Protected Attributes inherited from LocalRule

- CellularAutomataBase ∗ **parentCellularAutomata**
- StateSet ∗ **stateSet**

17.433.1 Member Function Documentation

17.433.1.1 applyRule()

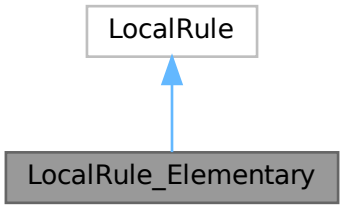
```
void LocalRule_CopyCurrentState::applyRule (
            Cell * cell )  [inline], [override], [virtual]
```

Pure virtual method that has to be overiden by derived class, responsable for applying the local rule to a cell.
Implements LocalRule.
The documentation for this class was generated from the following file:

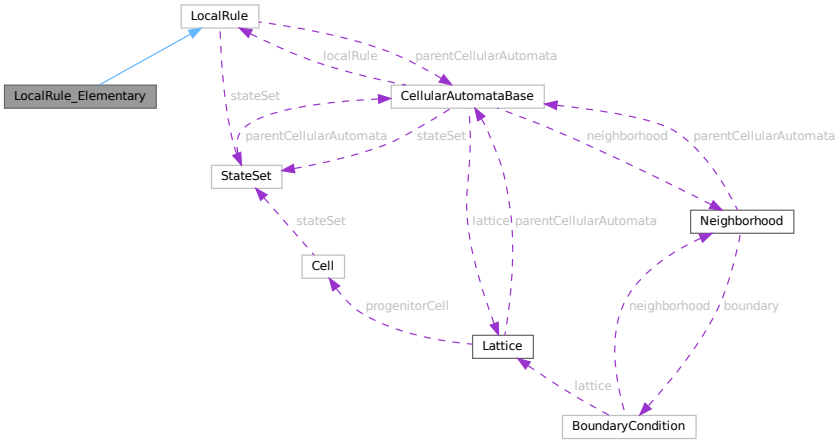
- applications/gui/genesys/cellular_automata/CellularAutomataDemoBuilder.h

17.434 LocalRule_Elementary Class Reference

Inheritance diagram for LocalRule_Elementary:



Collaboration diagram for LocalRule_Elementary:



Public Member Functions

- **LocalRule_Elementary** (CellularAutomataBase ∗parentCellularAutomata, uint8_t ruleNumber=30, StateSet ∗stateSet=nullptr)
- **LocalRule_Elementary** (const LocalRule_Elementary &orig)
- virtual void applyRule (Cell ∗cell) override

  Pure virtual method that has to be overiden by derived class, responsable for applying the local rule to a cell.

- uint8_t **getRuleNumber** () const
- void **setRuleNumber** (const uint8_t ruleNumber)

Public Member Functions inherited from LocalRule

- **LocalRule** (CellularAutomataBase *parentCellularAutomata, StateSet *stateSet=nullptr)
- **LocalRule** (const LocalRule &orig)
- void **setStateSet** (StateSet *stateSet)

Additional Inherited Members

Protected Attributes inherited from LocalRule

- CellularAutomataBase * **parentCellularAutomata**
- StateSet * **stateSet**

17.434.1 Member Function Documentation

17.434.1.1 applyRule()

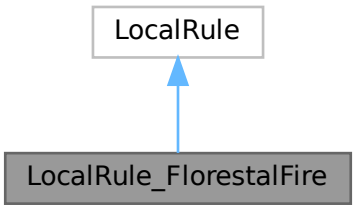
```
virtual void LocalRule_Elementary::applyRule (
            Cell * cell )  [inline], [override], [virtual]
```

Pure virtual method that has to be overiden by derived class, responsable for applying the local rule to a cell.
Implements LocalRule.
The documentation for this class was generated from the following file:

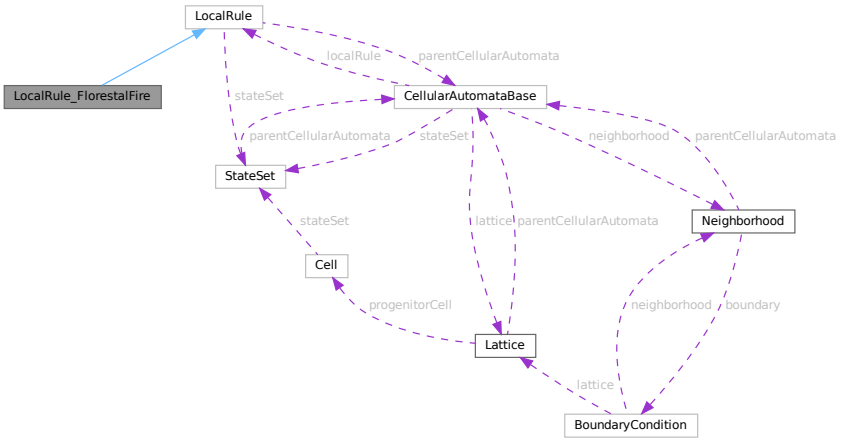
- plugins/components/ModalModel/CellularAutomata/LocalRule_Elementary.h

17.435 LocalRule_FlorestalFire Class Reference

Inheritance diagram for LocalRule_FlorestalFire:



Collaboration diagram for LocalRule_FlorestalFire:



Public Member Functions

- **LocalRule_FlorestalFire** (CellularAutomataBase ∗parentCellularAutomata)
- **LocalRule_FlorestalFire** (const LocalRule_FlorestalFire &orig)
- virtual void applyRule (Cell ∗cell) override

  Pure virtual method that has to be overiden by derived class, responsable for applying the local rule to a cell.

Public Member Functions inherited from LocalRule

- **LocalRule** (CellularAutomataBase ∗parentCellularAutomata, StateSet ∗stateSet=nullptr)
- **LocalRule** (const LocalRule &orig)

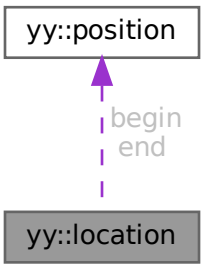
17.441 yy::location Class Reference

Two points in a source file.
`#include <parser/location.hh>`

Collaboration diagram for yy::location:



Public Types

- typedef position::filename_type **filename_type**

  Type for file name.
- typedef position::counter_type **counter_type**

  Type for line and column numbers.

Public Member Functions

- **location** (const position &b, const position &e)

  Construct a location from b to e.
- **location** (const position &p=position())

  Construct a 0-width location in p.
- **location** (filename_type *f, counter_type l=1, counter_type c=1)

  Construct a 0-width location in f, l, c.
- void **initialize** (filename_type *f=YY_NULLPTR, counter_type l=1, counter_type c=1)

  Initialization.

Line and Column related manipulators

- void **step** ()

  Reset initial location to final location.
- void **columns** (counter_type count=1)

  Extend the current location to the COUNT next columns.
- void **lines** (counter_type count=1)

  Extend the current location to the COUNT next lines.

Public Attributes

- position **begin**

  Beginning of the located region.
- position **end**

  End of the located region.

17.441.1 Detailed Description

Two points in a source file.
The documentation for this class was generated from the following file:

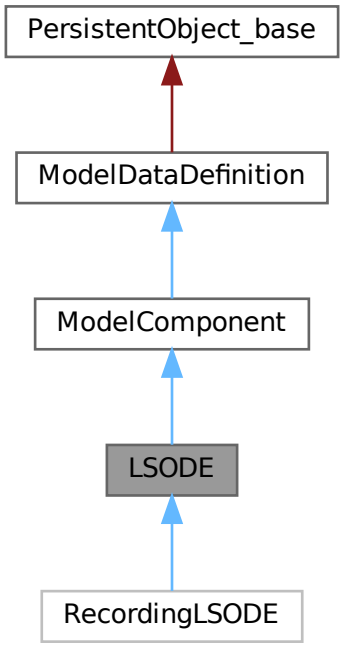
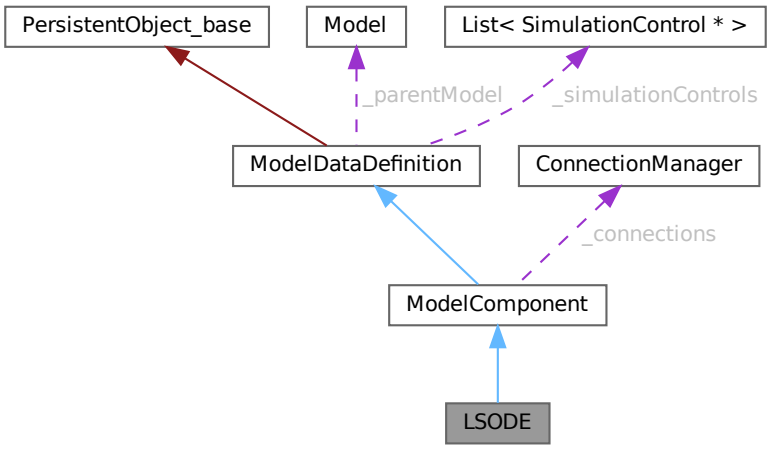
17.444 LSODE Class Reference

```
#include <plugins/components/Continuous/LSODE.h>
```

Inheritance diagram for LSODE:



Collaboration diagram for LSODE:



Public Member Functions

- **LSODE** (Model *model, std::string name="")
- virtual std::string show () override

  virtual public methods

- void **setTimeVariable** (Variable *_timeVariable)
- Variable * **getTimeVariable** () const
- void **setStep** (double _step)
- double **getStep** () const
- void **setVariable** (Variable *_variables)
- Variable * **getVariable** () const
- List< std::string > * **getDiffEquations** () const
- void **addDiffEquation** (std::string newDiffEquation)
- void **removeDiffEquation** (std::string diffEquation)
- void **setFilename** (std::string filename)
- std::string **getFileName** () const

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual ParserChangesInformation * _getParserChangesInformation ()
- virtual void _initBetweenReplications ()

17.444.1 Detailed Description

This component ...

17.444.2 Member Function Documentation

17.444.2.1 _check()

```
bool LSODE::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.444.2.2 _loadInstance()

```
bool LSODE::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.444.2.3 _onDispatchEvent()

```
void LSODE::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.
Reimplemented in RecordingLSODE.

17.444.2.4 _saveInstance()

```
void LSODE::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.444.2.5 show()

```
std::string LSODE::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

- plugins/components/Continuous/LSODE.h
- plugins/components/Continuous/LSODE.cpp

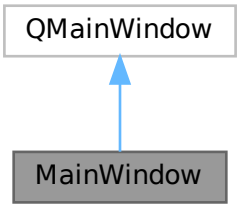
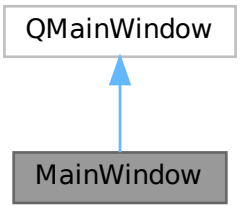
17.447 MainWindow Class Reference

Main Qt window that composes controllers/services and preserves legacy GUI entry points.

`#include <applications/gui/genesys/mainwindow.h>`
Inheritance diagram for MainWindow:



Collaboration diagram for MainWindow:



Public Member Functions

- **MainWindow** (QWidget *parent=nullptr)

  Builds the composition root, wiring controllers/services and legacy Qt surface.
- ~**MainWindow** ()

  Releases UI resources while preserving existing Qt ownership semantics.
- ModelGraphicsScene * **myScene** () const

  Returns the current model graphics scene used by delegated controllers/services.
- bool **graphicalModelHasChanged** () const

  Indicates whether graphical representation has unsaved modifications.
- void **setGraphicalModelHasChanged** (bool graphicalModelHasChanged)

  Updates graphical-change flag used by persistence/action synchronization.
- void **unselectDrawIcons** ()

  Compatibility wrapper that clears currently selected draw tool actions.
- bool **checkSelectedDrawIcons** ()

  Compatibility wrapper that reports whether any draw tool action is selected.
- void **refreshGuiExtensions** ()

  Public refresh hook for graphical extension contributions.
- void **refreshPluginCatalog** ()

  Public refresh hook for plugin catalog tree.

Protected Member Functions

- void **closeEvent** (QCloseEvent ∗event) override

Friends

- class **SimulationEventController**

17.447.1 Detailed Description

Main Qt window that composes controllers/services and preserves legacy GUI entry points.
MainWindow remains the composition root of GenesysQtGUI: it owns the generated UI, wires extracted controllers/services, and exposes the original Qt slot surface expected by actions, widgets, and kernel callback registration. In the refactored architecture it primarily acts as a compatibility façade that delegates operational responsibilities to focused collaborators.
Responsibilities:

- bootstrap UI construction and dependency wiring for controllers/services;
- host compatibility wrappers used by menus/toolbars/scene callbacks;
- coordinate cross-cutting state that still spans multiple controllers.

Boundaries:

- detailed domain workflows (simulation commands, lifecycle, persistence, scene tools, property editing, trace/event rendering) are delegated to dedicated controller/service classes whenever extraction already exists;
- MainWindow does not replace kernel ownership semantics.

The documentation for this class was generated from the following files:

- applications/gui/genesys/mainwindow.h
- applications/gui/genesys/mainwindow.cpp
- applications/gui/genesys/mainwindow_controller.cpp
- applications/gui/genesys/mainwindow_modelrepresentations.cpp

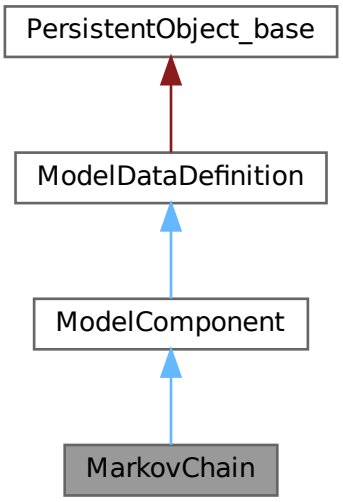
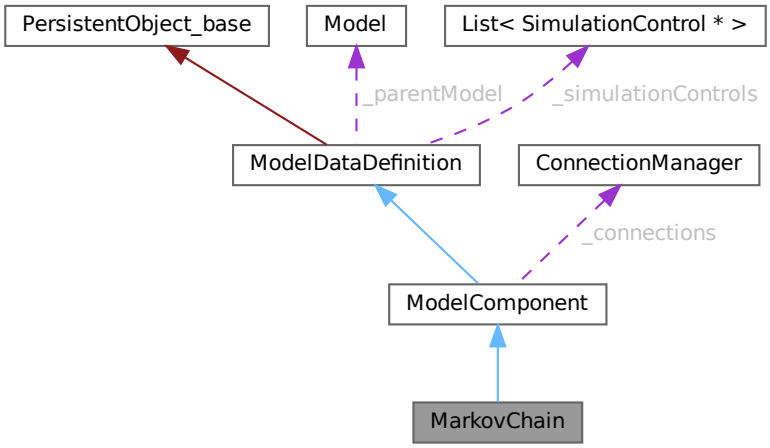
17.452 MarkovChain Class Reference

Inheritance diagram for MarkovChain:



Collaboration diagram for MarkovChain:



Public Member Functions

- **MarkovChain** (Model *model, std::string name="")
- virtual std::string show () override

  virtual public methods
- void **setTransitionProbabilityMatrix** (ModelDataDefinition *transitionMatrix)
- ModelDataDefinition * **getTransitionMatrix** () const
- void **setInitialDistribution** (ModelDataDefinition *initialDistribution)
- ModelDataDefinition * **getInitialDistribution** () const
- void **setCurrentState** (ModelDataDefinition *currentState)
- ModelDataDefinition * **getCurrentState** () const

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insertIntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecificEnabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual void _initBetweenReplications () override

17.452.1 Member Function Documentation

17.452.1.1 _check()

```
bool MarkovChain::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.452.1.2 _createEditableDataDefinitions()

```
void MarkovChain::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.452.1.3 _initBetweenReplications()

```
void MarkovChain::_initBetweenReplications ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.452.1.4 _loadInstance()

```
bool MarkovChain::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.452.1.5 _onDispatchEvent()

```
void MarkovChain::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.452.1.6 _saveInstance()

```
void MarkovChain::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.452.1.7 show()

```
std::string MarkovChain::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

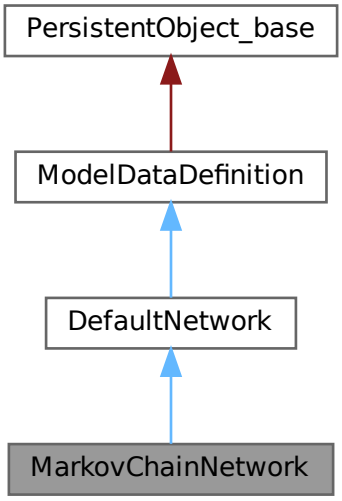
Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

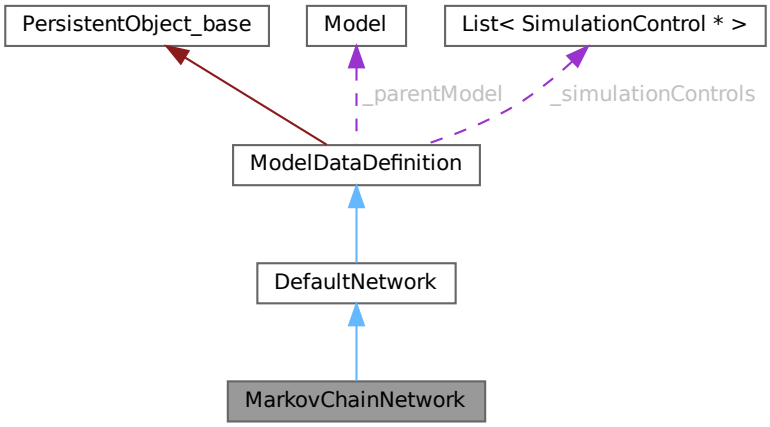
- plugins/components/AnalyticalModeling/MarkovChain.h
- plugins/components/AnalyticalModeling/MarkovChain.cpp

17.453 MarkovChainNetwork Class Reference

Finite time-homogeneous Discrete-Time Markov Chain network.
`#include <plugins/data/ModalModel/MarkovChainNetwork.h>`
Inheritance diagram for MarkovChainNetwork:



Collaboration diagram for MarkovChainNetwork:



Classes

- class MarkovTransition

Public Member Functions

- **MarkovChainNetwork** (Model *model, std::string name="")
- void **addState** (MarkovState *state)
- void **removeState** (MarkovState *state)
- List< MarkovState * > * **getStates** () const
- void **addTransition** (MarkovTransition *transition)

- MarkovState * **getCurrentState** () const
- unsigned int **getStateIndex** (MarkovState *state) const
- MarkovState * **getStateAt** (unsigned int index) const
- double **getProbabilityTolerance** () const
- void **setProbabilityTolerance** (double tolerance)
- void **resetSampler** ()
- virtual std::string show () override

  Returns a textual representation of this data definition.

Public Member Functions inherited from DefaultNetwork

- **DefaultNetwork** (Model *model, std::string name="", std::string dataDefinitionTypename=Util::TypeOf< DefaultNetwork >())
- unsigned int **addInputPort** (const std::string &portName)

  Declares a new input port; returns its 0-based index. Rejects a duplicate name (returns the existing index instead of creating a duplicate).
- unsigned int **addOutputPort** (const std::string &portName)

Declares a new output port; returns its 0-based index. Rejects a duplicate name (returns the existing index instead of creating a duplicate).

- unsigned int **getNumInputPorts** () const
- unsigned int **getNumOutputPorts** () const
- std::string **getInputPortName** (unsigned int index) const
- std::string **getOutputPortName** (unsigned int index) const
- int **getInputPortIndex** (const std::string &portName) const

  Returns the input port index for `portName`, or -1 when not declared.
- int **getOutputPortIndex** (const std::string &portName) const

  Returns the output port index for `portName`, or -1 when not declared.
- double **getActivationCount** () const

  Number of times activate() has been called since the last replication reset.
- NetworkActivationResult activate (const NetworkActivationFrame &frame)

  Runs exactly one network activation for `frame`.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insertIntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.

- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

17.453.1 Detailed Description

Finite time-homogeneous Discrete-Time Markov Chain network.
One activation performs exactly one Markov step from the current state by sampling the outgoing transition probabilities of that state using the GenESyS sampler infrastructure. The current state belongs to the network, not to a process Entity attribute.
Transition ownership: `addTransition()` and persistence reload take exclusive ownership of heap-allocated `MarkovTransition` objects and delete them from the network destructor / reload / remove paths.

17.453.2 Member Function Documentation

17.453.2.1 _activate()

```
NetworkActivationResult MarkovChainNetwork::_activate (
            const NetworkActivationFrame & frame )  [override], [protected], [virtual]
```

Formalism-specific activation behavior.
The base implementation performs no state change and returns a result sized to `getNumOutputPorts()` with every output absent. Specializations override this to implement EFSM transition firing, one DTMC step, one CPN firing step, etc. Must not receive or depend on `Entity*` (architecture reference §8.4, §19).
Reimplemented from DefaultNetwork.

17.453.2.2 _check()

```
bool MarkovChainNetwork::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from DefaultNetwork.

17.453.2.3 _initBetweenReplications()

```
void MarkovChainNetwork::_initBetweenReplications ( )  [override], [protected], [virtual]
```

Reimplemented from DefaultNetwork.

17.453.2.4 _loadInstance()

```
bool MarkovChainNetwork::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from DefaultNetwork.

17.453.2.5 _saveInstance()

```
void MarkovChainNetwork::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from DefaultNetwork.

17.453.2.6 show()

`std::string MarkovChainNetwork::show ( ) [override], [virtual]`
Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from DefaultNetwork.
The documentation for this class was generated from the following files:

- plugins/data/ModalModel/MarkovChainNetwork.h
- plugins/components/ModalModel/MarkovChainNetwork.cpp

17.454 MarkovState Class Reference

State node used by MarkovChainNetwork DTMC models.

  virtual public methods

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model ∗model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ∼**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.

- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

17.456.1 Detailed Description

ODE system generated from biochemical reactions using mass-action kinetics.

17.456.2 Member Function Documentation

17.456.2.1 dimension()

```
unsigned int MassActionOdeSystem::dimension ( ) const  [inline], [override], [virtual]
```

Implements OdeSystem_if.

17.456.2.2 evaluate()

```
void MassActionOdeSystem::evaluate (
            double ,
            const double * y,
            double * dydt ) const  [inline], [override], [virtual]
```

Implements OdeSystem_if.

The documentation for this class was generated from the following file:

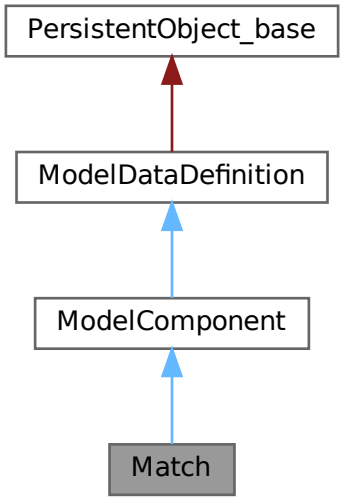
- tools/Biochemical/MassActionOdeSystem.h

17.457 Match Class Reference

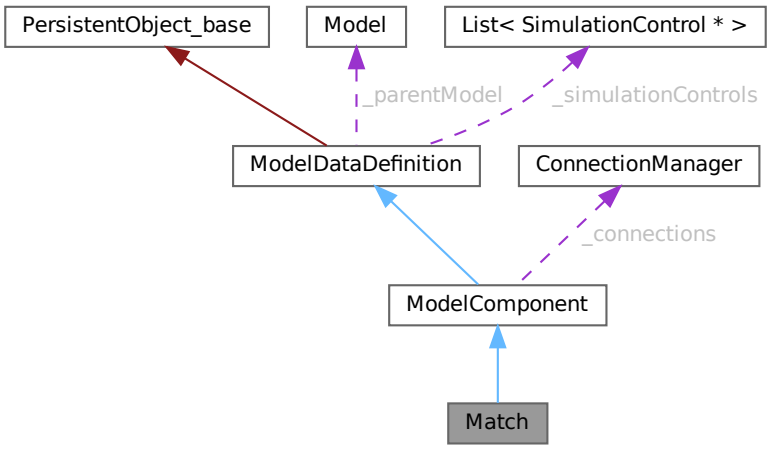
Brings together one entity from each of several input queues, optionally requiring a matching attribute value, and releases them in sync.

```
#include <plugins/components/Synchronization/Match.h>
```

Inheritance diagram for Match:



Collaboration diagram for Match:



Public Types

- enum class **Rule** : int { **Any** = 0 , **ByAttribute** = 1 , **num_elements** = 2 }

Public Member Functions

- **Match** (Model ∗model, std::string name="")
- virtual std::string show () override

  virtual public methods

- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- void **setRule** (Match::Rule _rule)
- Match::Rule **getRule** () const
- void **setAttributeName** (std::string _attributeName)
- std::string **getAttributeName** () const

- unsigned int **getNumberOfQueues** () const

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

17.457.1 Detailed Description

Brings together one entity from each of several input queues, optionally requiring a matching attribute value, and releases them in sync.
Arena correspondence: the "Match module" (Rockwell Automation, *Getting Started with Arena*, "The Advanced Process Panel", p. 56). `Rule` (`Any/ByAttribute`) and `_attributeName` match Arena's Type/Attribute Name; `_matchSize` matches Number to Match; `_numberOfQueues` generalizes Arena's fixed five-queue limit to an arbitrary count.

17.457.2 Member Function Documentation

17.457.2.1 _check()

```
bool Match::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.457.2.2 _createEditableDataDefinitions()

```
void Match::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.457.2.3 _loadInstance()

```
bool Match::_loadInstance (
            PersistenceRecord * fields )  [override], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.457.2.4 _onDispatchEvent()

```
void Match::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.457.2.5 _saveInstance()

```
void Match::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.457.2.6 show()

```
std::string Match::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

- plugins/components/Synchronization/Match.h
- plugins/components/Synchronization/Match.cpp

17.458 testing::Message Class Reference

Public Member Functions

- const std::map< std::string, double > & **getLastFluxes** () const
- virtual std::string show () override

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model ∗model, std::string componentTypename, std::string name="")

  constructors
- virtual ∼**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager ∗ getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent ∗component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

Returns the free-form description associated with this component.

- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insertIntoModel=true)

  Creates a model data definition and optionally inserts it into the model.

- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.

- Util::identification getId () const

  Returns the unique identifier of this instance.

- void setName (const std::string &name)

  Updates the logical name of this instance.

- const std::string & getName () const

  Returns the logical name of this instance.

- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.

- const std::string & getLabel () const

  Returns the user-visible label of this instance.

- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.

- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.

- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.

- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.

- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.

- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.

- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.

- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.

- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.

- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.

- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecificEnabled=true)

Defines the specific trace level and optionally enables it immediately.

- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.

- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component

- static bool Check (ModelComponent *component)

  Validates a component instance.

- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.

- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.

- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.

- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.

- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.

- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.

- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.

- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.

- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden

- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.

- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes

- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.

- virtual void _createEditableDataDefinitions () override

Protected Member Functions inherited from ModelDataDefinition

17.459.1 Detailed Description

Component that evaluates flux-balance analysis (FBA) over a MetabolicNetwork.

17.459.1.1 LP solver dependency (GLPK)

MetabolicFluxBalance requires GLPK for metabolic networks with more than a few dozen reactions (e.g., M. genitalium: 641 reactions; yeast-GEM: 4131 reactions). Without GLPK, a built-in basis-enumeration fallback is used, which is only practical for small toy networks.

17.459.1.1.1 Installation

Ubuntu/Debian: sudo apt-get install libglpk-dev Fedora/RHEL: sudo dnf install glpk-devel macOS (Brew): brew install glpk

17.459.1.1.2 Re-configuration after installation

cmake –preset terminal-app # or any other preset cmake –build build/terminal-app –target genesys_plugins_↩components
CMake will print at configure time: GenESyS: GLPK found — MetabolicFluxBalance ... will use GLPK LP solver or: GenESyS: GLPK not found — ... (suitable for small models only; install libglpk-dev ...)
The preprocessor guard is GENESYS_HAVE_GLPK. The GLPK solver wrapper is in source/tools/Biochemical/GlpkFluxBalanceSolver

17.459.2 Member Function Documentation

17.459.2.1 _check()

```
bool MetabolicFluxBalance::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.459.2.2 _createEditableDataDefinitions()

```
void MetabolicFluxBalance::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.459.2.3 _loadInstance()

```
bool MetabolicFluxBalance::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.459.2.4 _onDispatchEvent()

```
void MetabolicFluxBalance::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.459.2.5 _saveInstance()

```
void MetabolicFluxBalance::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.459.2.6 show()

```
std::string MetabolicFluxBalance::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

- plugins/components/BiochemicalSimulation/MetabolicFluxBalance.h
- plugins/components/BiochemicalSimulation/MetabolicFluxBalance.cpp

17.460 MetabolicFluxBalanceSolver Class Reference

```
#include <tools/Biochemical/MetabolicFluxBalanceSolver.h>
```

Classes

- struct Problem
- struct Solution

Static Public Member Functions

- static Solution **solve** (const Problem &problem)

17.460.1 Detailed Description

Small LP solver for flux-balance problems with equality constraints and variable bounds.
It solves: maximize/minimize c^T v subject to A v = 0 lb <= v <= ub
using basis enumeration over bounded vertices. This is practical for the small metabolic models currently exercised by the runtime tests and provides a concrete solver-backed replacement for the previous stub objective logic.
The documentation for this class was generated from the following file:

- tools/Biochemical/MetabolicFluxBalanceSolver.h

17.461.1 Detailed Description

Aggregate metabolic network definition.
A MetabolicNetwork stores the reaction membership and objective metadata for future flux-balance style components.

17.461.2 Member Function Documentation

17.461.2.1 _check()

```
bool MetabolicNetwork::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.461.2.2 _createEditableDataDefinitions()

```
void MetabolicNetwork::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.461.2.3 _loadInstance()

```
bool MetabolicNetwork::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.461.2.4 _saveInstance()

```
void MetabolicNetwork::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.

17.461.2.5 show()

```
std::string MetabolicNetwork::show ( )  [override], [virtual]
```

Returns a textual representation of this data definition.

Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from ModelDataDefinition.
The documentation for this class was generated from the following files:

- plugins/data/BiochemicalSimulation/MetabolicNetwork.h
- plugins/data/BiochemicalSimulation/MetabolicNetwork.cpp

- void **setObjectiveCoefficient** (double objectiveCoefficient)
- double **getObjectiveCoefficient** () const
- void **setReversible** (bool reversible)
- bool **isReversible** () const
- void **setGeneRule** (std::string geneRule)
- std::string **getGeneRule** () const
- virtual std::string show () override

  Returns a textual representation of this data definition.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.

- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static ModelDataDefinition * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static PluginInformation * **GetPluginInformation** ()
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  must be overriden by derived classes
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.

17.462.1 Detailed Description

Constraint-based metabolic reaction definition.

17.462.2 Member Function Documentation

17.462.2.1 _check()

```
bool MetabolicReaction::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.462.2.2 _createEditableDataDefinitions()

```
void MetabolicReaction::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.462.2.3 _loadInstance()

```
bool MetabolicReaction::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.462.2.4 _saveInstance()

```
void MetabolicReaction::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.

17.462.2.5 show()

```
std::string MetabolicReaction::show ( )  [override], [virtual]
```

Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from ModelDataDefinition.
The documentation for this class was generated from the following files:

- plugins/data/BiochemicalSimulation/MetabolicReaction.h
- plugins/data/BiochemicalSimulation/MetabolicReaction.cpp

17.463 MetabolicStateProjectionComponent Class Reference

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

17.463.1 Detailed Description

Projects flux-balance outputs into a WholeCellState.
MetabolicStateProjectionComponent bridges FBA-style submodels with the whole-cell shared state. It reads the latest objective value and reaction fluxes computed by a MetabolicFluxBalance component and writes selected projections into WholeCellState as:

- global metabolite proxies;
- compartment-specific metabolite proxies;
- pathway activity summaries.

This component intentionally does not solve the metabolic optimization itself. It only transfers selected results to the whole-cell layer so that growth, checkpoints, and gene-expression submodels can consume them.

17.463.2 Member Function Documentation

17.463.2.1 _check()

```
bool MetabolicStateProjectionComponent::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.463.2.2 _createEditableDataDefinitions()

```
void MetabolicStateProjectionComponent::_createEditableDataDefinitions ( )  [override], [protected],
[virtual]
```

Reimplemented from ModelDataDefinition.

17.463.2.3 _loadInstance()

```
bool MetabolicStateProjectionComponent::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.463.2.4 _onDispatchEvent()

```
void MetabolicStateProjectionComponent::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.463.2.5 _saveInstance()

```
void MetabolicStateProjectionComponent::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.463.2.6 show()

`std::string MetabolicStateProjectionComponent::show ( ) [override], [virtual]`
virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

- plugins/components/WholeCellModeling/MetabolicStateProjectionComponent.h
- plugins/components/WholeCellModeling/MetabolicStateProjectionComponent.cpp

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecificEnabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes
- virtual void _initBetweenReplications () override
- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual void _createEditableDataDefinitions () override

17.464.1 Detailed Description

Minimal metabolic submodel that produces ATP and NADPH each step.
Replaces a full FBA step with a volume-proportional energy production model calibrated for M. genitalium (Karr et al. 2012):
ATP_produced = atpYieldRate × cellVolume(fL) × deltaT [mmol] ATP_pool(new) = min(ATP_pool + ATP_produced − ATP_consumed, atpPoolMax)
ATP consumption is estimated as a fixed fraction of the current pool (consumption rate = consumptionFraction × ATP_pool).
Results are written to the WholeCellState metabolite pool under keys "ATP" and "ADP". Downstream components can read "ATP" to gate reactions.
For a full FBA integration, replace this component with a proper MetabolicFluxBalance + network wiring. This component is intentionally minimal so that Phases 2–5 can be validated without GLPK-specific setup.

17.464.2 Member Function Documentation

17.464.2.1 _check()

```
bool MetabolicSubmodelComponent::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.464.2.2 _createEditableDataDefinitions()

```
void MetabolicSubmodelComponent::_createEditableDataDefinitions ( )  [override], [protected],
[virtual]
```

Reimplemented from ModelDataDefinition.

17.464.2.3 _initBetweenReplications()

```
void MetabolicSubmodelComponent::_initBetweenReplications ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.464.2.4 _loadInstance()

```
bool MetabolicSubmodelComponent::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.464.2.5 _onDispatchEvent()

```
void MetabolicSubmodelComponent::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.464.2.6 _saveInstance()

```
void MetabolicSubmodelComponent::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.464.2.7 show()

```
std::string MetabolicSubmodelComponent::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.

17.467.1 Detailed Description

Process-world adapter that activates an attached DefaultNetwork.
Network topology and formalism state live in the attached network. This component only maps entity arrivals to network activations and routes network outputs back into the process model.

17.467.2 Member Function Documentation

17.467.2.1 _check()

```
bool ModalModelDefault::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.467.2.2 _createAttachedAttributes()

```
void ModalModelDefault::_createAttachedAttributes ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.467.2.3 _initBetweenReplications()

```
void ModalModelDefault::_initBetweenReplications ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.467.2.4 _loadInstance()

```
bool ModalModelDefault::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.467.2.5 _onDispatchEvent()

```
void ModalModelDefault::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.467.2.6 _saveInstance()

```
void ModalModelDefault::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.467.2.7 show()

```
std::string ModalModelDefault::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

- plugins/components/ModalModel/ModalModelDefault.h
- plugins/components/ModalModel/ModalModelDefault.cpp

17.468 Model Class Reference

```
#include <kernel/simulator/model/Model.h>
```

Public Member Functions

- Model (Simulator *simulator, unsigned int level=0)

  Creates a model bound to a simulator.
- virtual ~**Model** ()

  Releases model-owned runtime state.
- bool save (std::string filename)

  Saves the model to a file.
- bool load (std::string filename)

  Loads the model from a file.
- bool check ()

  Validates the model structure and configuration.
- void **clear** ()

  Clears the current model content.
- std::string showLanguage ()

  Returns the model specification in the source language.
- void **show** ()

  Displays the model contents to the configured trace output.
- bool insert (ModelDataDefinition *elemOrComp)

  Inserts a model data definition or component into the model.
- void remove (ModelDataDefinition *elemOrComp)

  Removes a model data definition or component from the model.
- std::list< ModelDataDefinition * > collectDataDefinitionsRemovedWith (const std::list< ModelDataDefinition * > &roots) const

  Computes the data definitions that should be removed together with a set of roots.
- Entity * createEntity (std::string name, bool insertIntoModel=true)

  Creates an entity owned by this model.
- void removeEntity (Entity *entity)

  Removes an entity owned by this model.
- void sendEntityToComponent (Entity *entity, Connection *connection, double timeDelay=0.0)

  Schedules an entity transfer through a specific connection.
- void sendEntityToComponent (Entity *entity, ModelComponent *component, double timeDelay=0.0, unsigned int componentinputPortNumber=0)

Schedules an entity transfer to a specific component and input port.

- double parseExpression (const std::string expression)

  Parses and evaluates an expression.
- double parseExpression (const std::string expression, bool &success, std::string &errorMessage)

  Parses and evaluates an expression while reporting success or failure.
- bool checkExpression (const std::string expression, const std::string expressionName, std::string &error↩ Message)

  Checks whether an expression is syntactically valid.
- void checkReferencesToDataDefinitions (std::string expression, std::map< std::string, std::list< std::string > * > *referencedDataDefinitions)

  Collects data-definition references found in an expression.
- Util::identification getId () const

  Returns the unique model identifier.
- bool hasChanged () const

  Indicates whether the model has pending changes.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for the model and its owned persistent objects.
- OnEventManager * getOnEventManager () const

  Returns the event manager that coordinates model-level events.
- ModelDataManager * getDataManager () const

  Returns the data manager for model data definitions.
- ModelComponentManager * getComponentManager () const

  Returns the component manager for model components.
- ModelInfo * getInfos () const

  Returns the model metadata object.
- Simulator * getParentSimulator () const

  Returns the parent simulator that owns this model.
- ModelSimulation * getSimulation () const

  Returns the simulation controller associated with this model.
- List< Event * > * getFutureEvents () const

  Returns the future-event queue.
- List< SimulationControl * > * getControls () const

  Returns the simulation controls exposed by the model.
- List< SimulationResponse * > * getResponses () const

  Returns the simulation responses exposed by the model.
- void setTracer (TraceManager *_traceManager)

  Sets the trace manager used by this model.
- TraceManager * getTracer () const

  Returns the trace manager used by this model.
- Persistence_if * getPersistence () const

  Returns the persistence interface used by this model.
- unsigned int getLevel () const

  Returns the hierarchy level of the model.

17.468.1 Detailed Description

Model is probably the most important class of Genesys kernel. It represents a discrete event-driven simulation model. Each model is responsible for controlling its own simulation, ie, for sequentially processing events and collecting statistical results. A model is mainly represented by a collection of components (ModelComponent), adequately configurated and connected, and a collection of under layered modeldatum (ModelDataDefinition).

17.468.2 Constructor & Destructor Documentation

17.468.2.1 Model()

```
Model::Model (
            Simulator * simulator,
            unsigned int level = 0 )
```

Creates a model bound to a simulator.

Parameters

simulator	Parent simulator that owns the model.
level	Hierarchy level of the model within the simulator.

17.468.3 Member Function Documentation

17.468.3.1 check()

```
bool Model::check ( )
```

Validates the model structure and configuration.
Checks the integrity and consistency of the model, may correct some inconsistencies, and returns whether the model is ready to be simulated.

Returns

`true` when the model is ready to simulate.

17.468.3.2 checkExpression()

```
bool Model::checkExpression (
            const std::string expression,
            const std::string expressionName,
            std::string & errorMessage )
```

Checks whether an expression is syntactically valid.
This method is invoked by ModelComponents and ModelDatas in their private _check() methods to validate user-defined expressions.

Parameters

expression	Expression text.
expressionName	Logical name used in diagnostics.
errorMessage	Output error message when validation fails.

Returns

`true` when the expression is valid.

17.468.3.3 checkReferencesToDataDefinitions()

```
void Model::checkReferencesToDataDefinitions (
            std::string expression,
            std::map< std::string, std::list< std::string > * > * referencedDataDefinitions
)
```

Collects data-definition references found in an expression.

Parameters

expression	Expression text.

Parameters

referencedDataDefinitions	Output map of referenced data definitions by name.

17.468.3.4 collectDataDefinitionsRemovedWith()

```
std::list< ModelDataDefinition * > Model::collectDataDefinitionsRemovedWith (
            const std::list< ModelDataDefinition * > & roots ) const
```

Computes the data definitions that should be removed together with a set of roots.

Parameters

roots	Root objects selected for removal.

Returns

Flattened list of dependent data definitions to remove as well.

17.468.3.5 createEntity()

```
Entity * Model::createEntity (
            std::string name,
            bool insertIntoModel = true )
```

Creates an entity owned by this model.

Parameters

name	Entity name.
insertIntoModel	If `true`, inserts the entity into the model immediately.

Returns

Newly created entity.

17.468.3.6 getComponentManager()

```
ModelComponentManager * Model::getComponentManager ( ) const
```

Returns the component manager for model components.

Returns

Component manager instance.

17.468.3.7 getControls()

```
List< SimulationControl * > * Model::getControls ( ) const
```

Returns the simulation controls exposed by the model.
These are the values that can be externally controlled and usually correspond to input parameters that must be changed for an experimental design.

Returns

List of writable simulation controls.

17.468.3.8 getDataManager()

```
ModelDataManager * Model::getDataManager ( ) const
```

Returns the data manager for model data definitions.
Provides access to the class that manages the basic elements of the simulation model, such as queues, resources, variables and similar model data definitions.

Returns

Data manager instance.

17.468.3.9 getFutureEvents()

```
List< Event * > * Model::getFutureEvents ( ) const
```

Returns the future-event queue.
The future events list is chronologically sorted. Events are scheduled by components while processing other events, and a replication evolves by sequentially processing the first event in this list. The list is initialized with the events first described by source components.

Returns

Chronologically ordered list of scheduled events.

17.468.3.10 getId()

```
Util::identification Model::getId ( ) const
```

Returns the unique model identifier.

Returns

Model identifier.

17.468.3.11 getInfos()

```
ModelInfo * Model::getInfos ( ) const
```

Returns the model metadata object.

Returns

Model info instance.

17.468.3.12 getLevel()

```
unsigned int Model::getLevel ( ) const
```

Returns the hierarchy level of the model.
Provides access to the class that performs the trace of simulation and replications.

Returns

Model level.

17.468.3.13 getOnEventManager()

```
OnEventManager * Model::getOnEventManager ( ) const
```

Returns the event manager that coordinates model-level events.
Provides access to the class that manages events generated by the model, such as the beginning of a new simulation or replication and the processing of an event.

Returns

On-event manager instance.

17.468.3.14 getParentSimulator()

```
Simulator * Model::getParentSimulator ( ) const
```

Returns the parent simulator that owns this model.

Returns

Parent simulator.

17.468.3.15 getPersistence()

```
Persistence_if * Model::getPersistence ( ) const
```

Returns the persistence interface used by this model.

Returns

Persistence interface instance.

17.468.3.16 getResponses()

```
List< SimulationResponse * > * Model::getResponses ( ) const
```

Returns the simulation responses exposed by the model.
These are the exits or simulation results that can be read externally and usually correspond to statistics gathered for an experimental design.

Returns

List of readable simulation responses.

17.468.3.17 getSimulation()

```
ModelSimulation * Model::getSimulation ( ) const
```

Returns the simulation controller associated with this model.
Provides access to the class that manages the model simulation.

Returns

Simulation controller instance.

17.468.3.18 getTracer()

```
TraceManager * Model::getTracer ( ) const
```

Returns the trace manager used by this model.

Returns

Trace manager instance.

17.468.3.19 hasChanged()

```
bool Model::hasChanged ( ) const
```

Indicates whether the model has pending changes.

Returns

`true` when the model or one of its owned objects changed.

17.468.3.20 insert()

```
bool Model::insert (
            ModelDataDefinition * elemOrComp )
```

Inserts a model data definition or component into the model.
This is a generic entry point for either ComponentManager->insert() or ModelDataManager->insert().

Parameters

elemOrComp	Object to insert.

Returns

`true` when the object was accepted.

17.468.3.21 load()

```
bool Model::load (
            std::string filename )
```

Loads the model from a file.

Parameters

filename	Input filename.

Returns

`true` when loading succeeds.

17.468.3.22 parseExpression() [1/2]

```
double Model::parseExpression (
            const std::string expression )
```

Parses and evaluates an expression.
The parser always returns a double, even when the expression has syntax errors, in which case the result is 0.

Parameters

expression	Expression text.

Returns

Numeric result of the expression, or 0 on syntax failure.

17.468.3.23 parseExpression() [2/2]

```
double Model::parseExpression (
            const std::string expression,
            bool & success,
            std::string & errorMessage )
```

Parses and evaluates an expression while reporting success or failure.
The parser always returns a double, even when the expression has syntax errors, in which case the result is 0. This overload also reports whether an error occurred.

Parameters

expression	Expression text.
success	Output flag that receives the parsing result.
errorMessage	Output error message when parsing fails.

Returns

Numeric result of the expression, or 0 on syntax failure.

17.468.3.24 remove()

```
void Model::remove (
            ModelDataDefinition * elemOrComp )
```

Removes a model data definition or component from the model.
This is a generic entry point for either ComponentManager->remove() or ModelDataManager->remove().

Parameters

elemOrComp	Object to remove.

17.468.3.25 removeEntity()

```
void Model::removeEntity (
            Entity * entity )
```

Removes an entity owned by this model.

Parameters

entity	Entity to remove.

17.468.3.26 save()

```
bool Model::save (
            std::string filename )
```

Saves the model to a file.

Parameters

filename	Output filename.

Returns

`true` when saving succeeds.

17.468.3.27 sendEntityToComponent() [1/2]

```
void Model::sendEntityToComponent (
            Entity * entity,
            Connection * connection,
            double timeDelay = 0.0 )
```

Schedules an entity transfer through a specific connection.
Used by components to send entities to the next connected component, or by the model itself while processing an event.

Parameters

entity	Entity to transfer.
connection	Destination connection.
timeDelay	Delay applied before the entity reaches the destination.

17.468.3.28 sendEntityToComponent() [2/2]

```
void Model::sendEntityToComponent (
            Entity * entity,
            ModelComponent * component,
            double timeDelay = 0.0,
            unsigned int componentinputPortNumber = 0 )
```

Schedules an entity transfer to a specific component and input port.
Used by components to send entities to the next connected component, or by the model itself while processing an event.

Parameters

entity	Entity to transfer.
component	Destination component.
timeDelay	Delay applied before the entity reaches the destination.
componentinputPortNumber	Destination input port number.

17.468.3.29 setHasChanged()

```
void Model::setHasChanged (
            bool hasChanged )
```

Updates the changed flag for the model and its owned persistent objects.

Parameters

hasChanged	New changed-state value.

17.468.3.30 setTracer()

```
void Model::setTracer (
            TraceManager * _traceManager )
```

Sets the trace manager used by this model.

Parameters

_traceManager	Trace manager instance.

17.468.3.31 showLanguage()

```
std::string Model::showLanguage ( )
```

Returns the model specification in the source language.

Returns

Textual model specification.

The documentation for this class was generated from the following files:

  checkLimits

17.469.1 Detailed Description

The ModelChecker is responsable for verifying the model consistency, fixing inconsistencies wheneaver possible

17.469.2 Member Function Documentation

17.469.2.1 checkActivationCode()

```
virtual bool ModelChecker_if::checkActivationCode ( )  [pure virtual]
```

checkActivationCode

Returns

Checks if the installed version has acquired a valid activation code for commercial use

Implemented in ModelCheckerDefaultImpl1.

17.469.2.2 checkAll()

```
virtual bool ModelChecker_if::checkAll ( )  [pure virtual]
```

checkAll

Returns

Invoques all other checks and returns true only if all of them returned true

Implemented in ModelCheckerDefaultImpl1.

17.469.2.3 checkConnected()

```
virtual bool ModelChecker_if::checkConnected ( )  [pure virtual]
```

checkConnected

Returns

Checks if components are consistently connected to other to form a valid process-oriented model, describing how entities proceed to the flow

Implemented in ModelCheckerDefaultImpl1.

17.469.2.4 checkLimits()

```
virtual bool ModelChecker_if::checkLimits ( )  [pure virtual]
```

checkLimits

Returns

Checks if the model (its components and elements) fits the limits based on the activation code

Implemented in ModelCheckerDefaultImpl1.

17.469.2.5 checkSymbols()

```
virtual bool ModelChecker_if::checkSymbols ( )  [pure virtual]
```

checkSymbols

Returns

Checks if user-defined strings for symbols required by components, usually expressions or functions, are valid or references existing and valid elements.

Implemented in ModelCheckerDefaultImpl1.
The documentation for this class was generated from the following file:

17.470.1 Member Function Documentation

17.470.1.1 checkActivationCode()

```
bool ModelCheckerDefaultImpl1::checkActivationCode ( )  [override], [virtual]
```

checkActivationCode

Returns

Checks if the installed version has acquired a valid activation code for commercial use

Implements ModelChecker_if.

17.470.1.2 checkAll()

```
bool ModelCheckerDefaultImpl1::checkAll ( )  [override], [virtual]
```

checkAll

Returns

Invoques all other checks and returns true only if all of them returned true

Implements ModelChecker_if.

17.470.1.3 checkConnected()

```
bool ModelCheckerDefaultImpl1::checkConnected ( )  [override], [virtual]
```

checkConnected

Returns

Checks if components are consistently connected to other to form a valid process-oriented model, describing how entities proceed to the flow

Implements ModelChecker_if.

17.470.1.4 checkLimits()

```
bool ModelCheckerDefaultImpl1::checkLimits ( )  [override], [virtual]
```

checkLimits

Returns

Checks if the model (its components and elements) fits the limits based on the activation code

Implements ModelChecker_if.

17.470.1.5 checkSymbols()

```
bool ModelCheckerDefaultImpl1::checkSymbols ( )  [override], [virtual]
```

checkSymbols

Returns

Checks if user-defined strings for symbols required by components, usually expressions or functions, are valid or references existing and valid elements.

Implements ModelChecker_if.

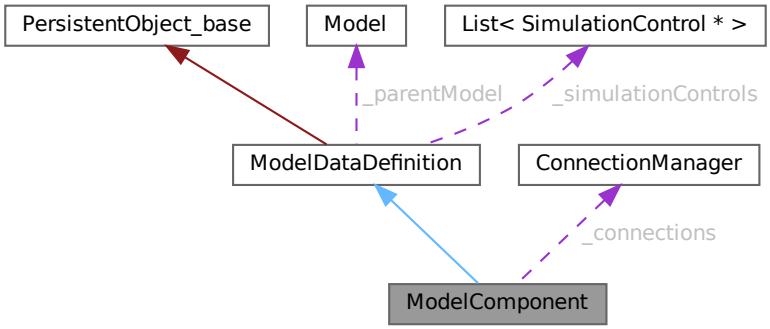
17.471 ModelComponent Class Reference

`#include <kernel/simulator/model/ModelComponent.h>`
Inherits ModelDataDefinition.
Inherited by AIAssistant, Access, Assign, BacteriaColony, Batch, BioRunnerCommand, BioSimulate, BioStateProjectionComponent, BioSteadyState, Buffer, CellCycleCheckpointComponent, CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CellularAutomataComp, Clone, CompartmentExchangeComponent, ContinuousSystemComponent, CppForG, Decide, Delay, DiffEquations, DiffusionSimulate, DropOff, DummyComponent, Enter, EukaryoticCellCycleComponent, Exit, FtsZPolymerizationComponent, GeneticCircuitSimulate, GeneticExpressionStep, LSODE, Leave, MarkovChain, Match, MetabolicFluxBalance, MetabolicStateProjectionComponent, MetabolicSubmodelComponent, ModalModelDefault, Move, PathwayStressResponseComponent, PickStation, Process, PythonForG, RSimulator, Record, Release, Remove, ResourceAllocationComponent, Route, SPICECircuit, SPICENode, Search, Seize, Separate, Signal, SinkModelComponent, SourceModelComponent, Start, StochasticReactionComponent, StochasticTranscription, StochasticTranslation, Stop, Store, Submodel, Unstore, Wait, and Write.

Collaboration diagram for ModelComponent:



Public Member Functions

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.
- virtual std::string show () override

  virtual public methods

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

Updates the user-visible label of this instance.

- const std::string & getLabel () const

  Returns the user-visible label of this instance.

- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.

- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.

- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.

- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.

- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.

- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.

- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.

- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.

- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.

- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.

- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.

- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.

- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component

- static bool Check (ModelComponent *component)

  Validates a component instance.

- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.

- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.

- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber)=0

  Handles a dispatched event for this component type.

Protected Member Functions inherited from ModelDataDefinition

17.471.1 Detailed Description

A component of the model is a block that represents a specific behavior to be simulated. The behavior is triggered when an entity arrives at the component, which corresponds to the occurrence of an event. A simulation model corresponds to a set of interconnected components to form the process by which the entity is submitted.

Parameters

model	The model this component belongs to

17.471.2 Constructor & Destructor Documentation

17.471.2.1 ModelComponent()

```
ModelComponent::ModelComponent (
            Model * model,
            std::string componentTypename,
            std::string name = "" )
```

constructors
Creates a model component and registers it in the component manager.

Parameters

model	Parent model.
componentTypename	Runtime type name for the concrete component.
name	Initial component name.

17.471.3 Member Function Documentation

17.471.3.1 _loadInstance()

```
bool ModelComponent::_loadInstance (
            PersistenceRecord * fields ) [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelDataDefinition.
Reimplemented in SinkModelComponent, SourceModelComponent, AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState, GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent, DiffEquations, DiffusionSimulate, LSODE, Decide, DropOff, Remove, Search, Buffer, Clone, Delay, Process, Release, Seize, SPICECircuit, Resistor, Vsource, Vpulse, Vsine, Capacitor, Diode, PMOS, NMOS, NOT, NAND, AND, NOR, OR, XOR, XNOR, SPICENode, CppForG, PythonForG, RSimulator, Batch, Separate, Record, Write, Assign, Create, Dispose, Access, Enter, Exit, Leave, Move, PickStation, Route, Start, Stop, Store, Unstore, CellularAutomataComp, ModalModelDefault, Submodel, Match, Signal, Wait, DummyComponent, BioStateProjectionComponent, CellCycleCheckpointComponent, CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CompartmentExchangeComponent, EukaryoticCellCycleComponent, FtsZPolymerizationComponent, MetabolicStateProjectionComponent, MetabolicSubmodelCompone PathwayStressResponseComponent, ResourceAllocationComponent, StochasticReactionComponent, StochasticTranscription, and StochasticTranslation.

17.471.3.2 _onDispatchEvent()

```
virtual void ModelComponent::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber ) [protected], [pure virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implemented in AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState,

GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent, DiffEquations, DiffusionSimulate, LSODE, Decide, DropOff, Remove, Search, Buffer, Clone, Delay, Process, Release, Seize, SPICECircuit, SPICENode, CppForG, PythonForG, RSimulator, Batch, Separate, Record, Write, Assign, Create, Dispose, Access, Enter, Exit, Leave, Move, PickStation, Route, Start, Stop, Store, Unstore, CellularAutomataComp, ModalModelDefault, Submodel, Match, Signal, Wait, DummyComponent, BioStateProjectionComponent, CellCycleCheckpointComponent, CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CompartmentExchangeComponent, EukaryoticCellCycleComponent, FtsZPolymerizationComponent, MetabolicStateProjectionComp MetabolicSubmodelComponent, PathwayStressResponseComponent, ResourceAllocationComponent, StochasticReactionCompone StochasticTranscription, StochasticTranslation, RecordingContinuousSystemComponent, RecordingContinuousSystemComponent, and RecordingLSODE.

17.471.3.3 _saveInstance()

```
void ModelComponent::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.
Reimplemented in SinkModelComponent, SourceModelComponent, AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState, GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent, DiffEquations, DiffusionSimulate, LSODE, Decide, DropOff, Remove, Search, Buffer, Clone, Delay, Process, Release, Seize, SPICECircuit, Resistor, Vsource, Vpulse, Vsine, Capacitor, Diode, PMOS, NMOS, NOT, NAND, AND, NOR, OR, XOR, XNOR, SPICENode, CppForG, PythonForG, RSimulator, Batch, Separate, Record, Write, Assign, Create, Dispose, Access, Enter, Exit, Leave, Move, PickStation, Route, Start, Stop, Store, Unstore, CellularAutomataComp, ModalModelDefault, Submodel, Match, Signal, Wait, DummyComponent, BioStateProjectionComponent, CellCycleCheckpointComponent, CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CompartmentExchangeComponent, EukaryoticCellCycleComponent, FtsZPolymerizationComponent, MetabolicStateProjectionComponent, MetabolicSubmodelCompone PathwayStressResponseComponent, ResourceAllocationComponent, StochasticReactionComponent, StochasticTranscription, and StochasticTranslation.

17.471.3.4 Check()

```
bool ModelComponent::Check (
            ModelComponent * component )  [static]
```

Validates a component instance.

Parameters

component	Component to validate.

Returns

`true` when the component is valid.

17.471.3.5 connectTo()

```
void ModelComponent::connectTo (
            ModelComponent * component,
            unsigned int inputPortNumber = 0 )
```

Connects this component to another component.

Parameters

component	Target component.
inputPortNumber	Input port number of the target component.

17.471.3.6 CreateInternalData()

```
void ModelComponent::CreateInternalData (
            ModelComponent * component ) [static]
```

Creates internal data required by a component instance.

Parameters

component	Component whose related data should be created.

17.471.3.7 DispatchEvent()

```
void ModelComponent::DispatchEvent (
            Event * event ) [static]
```

Dispatches a simulation event to the target component.
This method triggers the simulation behavior of the component. It is invoked when an event corresponding to this component is taken from the future events list or when an entity arrives through a connection.

Parameters

event	Event to process.

17.471.3.8 getConnectionManager()

```
ConnectionManager * ModelComponent::getConnectionManager ( ) const
```

new public user methods for this component
Returns the connection manager owned by this component.
This manager stores the components directly connected to the output. Usually a component has a single output, but it may have none (such as Dispose) or more than one (such as Decide). Along with each connected component, the manager stores the input port number where the entity will be sent. Usually components have a single input, but they may have none (such as Create) or more than one (such as Match).

Returns

Connection manager that stores outgoing connections.

17.471.3.9 getDescription()

```
std::string ModelComponent::getDescription ( ) const
```

Returns the free-form description associated with this component.

Returns

Description text.

17.471.3.10 hasBreakpointAt()

```
bool ModelComponent::hasBreakpointAt ( )
```

Indicates whether a simulation breakpoint is set on this component.

Returns

`true` when the simulation breakpoint list contains this component.

17.471.3.11 LoadInstance()

```
static ModelComponent * ModelComponent::LoadInstance (
            Model * model,
            PersistenceRecord * fields )  [static]
```

static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
Loads a component instance from serialized fields.

Parameters

model	Parent model that will own the component.
fields	Serialized fields for the component.

Returns

Newly created component instance.

17.471.3.12 remove()

```
void ModelComponent::remove (
            ModelComponent * comp )
```

Removes a connected component from this component.

Parameters

comp	Component to remove from the outgoing connection set.

17.471.3.13 SaveInstance()

```
void ModelComponent::SaveInstance (
            PersistenceRecord * fields,
            ModelComponent * component )  [static]
```

Serializes a component instance into a persistence record.

Parameters

fields	Output persistence record.
component	Component to serialize.

17.471.3.14 setDescription()

```
void ModelComponent::setDescription (
            std::string _description )
```

Updates the free-form description shown by the GUI.

Parameters

_description	New description text.

17.471.3.15 show()

```
std::string ModelComponent::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelDataDefinition.
Reimplemented in SourceModelComponent, AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState, GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent, DiffEquations, DiffusionSimulate, LSODE, Decide, DropOff, Remove, Search, Buffer, Clone, Delay, Process, Release, Seize, SPICECircuit, SPICENode, CppForG, PythonForG, RSimulator, Batch, Separate, Record, Write, Assign, Create, Dispose, Access, Enter, Exit, Leave, Move, PickStation, Route, Start, Stop, Store, Unstore, CellularAutomataComp, ModalModelDefault, Submodel, Match, Signal, Wait, DummyComponent, BioStateProjectionComponent, CellCycleCheckpointComponent, CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CompartmentExchangeComponent, EukaryoticCellCycleComponent, FtsZPolymerizationComponent, MetabolicStateProjectionComponent, MetabolicSubmodelComponent, PathwayStressResponseComponent, ResourceAllocationComponent, StochasticReactionComponent, StochasticTranscription, and StochasticTranslation.

17.471.4 Member Data Documentation

17.471.4.1 _connections

```
ConnectionManager* ModelComponent::_connections = new ConnectionManager()  [protected]
```

virtual protected methods that could be overriden by derived classes, if needed
This method is called by ModelChecker during model check. The component should check itself to verify if user parameters are ok (ex: correct syntax for the parser) and everithing in its parameters allow the model too run without errors in this component
This method returns all changes in the parser that are needed by plugins of this ModelDatas. When connecting a new plugin, ParserChangesInformation are used to change parser source code, whch is after compiled and dinamically linked to to simulator kernel to reflect the changes
This method is called by ModelSimulation when initianting the replication. The model should set all value for a new replication (Ex: setting back to 0 any internal counter, clearing lists, etc.
Legacy compatibility hook. Prefer the granular create* methods and the composed association manager.
This method is not used yet. It should be usefull for new UIs
The documentation for this class was generated from the following files:

- kernel/simulator/model/ModelComponent.h
- kernel/simulator/model/ModelComponent.cpp

17.472 ModelComponentManager Class Reference

Owns and organizes the set of `ModelComponent` objects in a model.
`#include <kernel/simulator/model/ModelComponentManager.h>`

Public Member Functions

- **ModelComponentManager** (Model *model)
  Creates a component manager attached to a model.

  getAllComponents

17.472.1 Detailed Description

Owns and organizes the set of `ModelComponent` objects in a model.
Provides insertion/removal, lookup and iteration helpers while tracking structural changes relevant to model validation/persistence workflows.

17.472.2 Member Function Documentation

17.472.2.1 begin()

`std::list< ModelComponent * >::iterator ModelComponentManager::begin ( )`
begin

Returns

Iterator to the first component.

17.472.2.2 clear()

`void ModelComponentManager::clear ( )`
clear
Removes all managed components from the model.

17.472.2.3 end()

`std::list< ModelComponent * >::iterator ModelComponentManager::end ( )`
end

Returns

Iterator past the last component.

17.472.2.4 find() [1/2]

```
ModelComponent * ModelComponentManager::find (
            std::string name )
```

find

Parameters

name	

Returns

Pointer to the component, or `nullptr` when not found.

17.472.2.5 find() [2/2]

```
ModelComponent * ModelComponentManager::find (
            Util::identification id )
```

find

Parameters

id	

Returns

Pointer to the component, or `nullptr` when not found.

17.472.2.6 front()

```
ModelComponent * ModelComponentManager::front ( )
```

front

Returns

First component in iteration order.

17.472.2.7 getAllComponents()

```
std::list< ModelComponent * > * ModelComponentManager::getAllComponents ( ) const
```

getAllComponents

Returns

17.472.2.8 getNumberOfComponents()

```
unsigned int ModelComponentManager::getNumberOfComponents ( )
```

getNumberOfComponents

Returns

Number of managed components.

17.472.2.9 getSourceComponents()

```
std::list< SourceModelComponent * > * ModelComponentManager::getSourceComponents ( )
```

getSourceComponents

Returns

17.472.2.10 getTransferInComponents()

```
std::list< ModelComponent * > * ModelComponentManager::getTransferInComponents ( )
```

getTransferInComponents

Returns

17.472.2.11 hasChanged()

```
bool ModelComponentManager::hasChanged ( ) const
```

hasChanged

Returns

17.472.2.12 insert()

```
bool ModelComponentManager::insert (
            ModelComponent * comp )
```

insert

Parameters

comp	

Returns

True when insertion succeeds.

17.472.2.13 next()

```
ModelComponent * ModelComponentManager::next ( )
```

next

Returns

Next component in iteration order.

17.472.2.14 remove()

```
void ModelComponentManager::remove (
            ModelComponent * comp )
```

remove

Parameters

comp	

17.472.2.15 setHasChanged()

```
void ModelComponentManager::setHasChanged (
            bool _hasChanged )
```

setHasChanged

Parameters

_hasChanged	

The documentation for this class was generated from the following files:

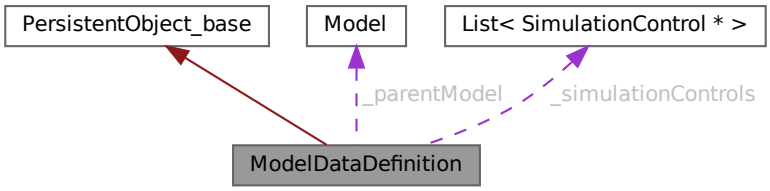
17.473 ModelDataDefinition Class Reference

`#include <kernel/simulator/model/ModelDataDefinition.h>`
Inherits PersistentObject_base.
Inherited by AISupport, Attribute, BacteriaSignalGrid, BioCompartment, BioNetwork, BioParameter, BioReaction, BioSimulatorRunner, BioSpecies, CPNArc, Conveyor, Counter, CppCompiler, DefaultNetwork, DefaultNode, DiffusionField, Distance, DummyElement, Entity, EntityGroup, EntityType, Failure, File, Formula, GeneticCircuit, GeneticCircuitPart, GeneticRegulation, GraphEdge, GroProgram, Label, MetabolicNetwork, MetabolicReaction, ModelComponent, MolecularSpecies, ODESolver, OLD_ODEelement, OctaveRunner, PythonRuntime, Queue, RSimulatorRunner, Resource, SPICERunner, Schedule, Segment, Sequence, Set, SignalData, Station, StatisticsCollector, StochasticReactionRule, Storage, Transporter, and WholeCellState.
Collaboration diagram for ModelDataDefinition:



Public Member Functions

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.

- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.
- virtual std::string show ()

  Returns a textual representation of this data definition.

Static Public Member Functions

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

Resets simulation-time state between replications.

- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.

- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- bool _getSaveDefaultsOption ()
- virtual bool _loadInstance (PersistenceRecord *fields) override

  must be overriden by derived classes

- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.

- virtual bool _check (std::string &errorMessage)

  could be overriden by derived classes

- virtual ParserChangesInformation * _getParserChangesInformation ()
- virtual void _initBetweenReplications ()
- virtual void _addSimulationControl (SimulationControl *control)

17.473.1 Detailed Description

This class is the basis for any modeldatum of the model (such as Queue, Resource, Variable, etc.) and also for any component of the model. It has the infrastructure to read and write on file and to verify symbols.

17.473.2 Constructor & Destructor Documentation

17.473.2.1 ModelDataDefinition()

```
ModelDataDefinition::ModelDataDefinition (
            Model * model,
            std::string datadefinitionTypename,
            std::string name = "",
            bool insertIntoModel = true )
```

Creates a model data definition and optionally inserts it into the model.

Parameters

model	Parent model that owns this data definition.
datadefinitionTypename	Runtime type name for the concrete data definition.
name	Initial object name.
insertIntoModel	If `true`, the new instance is registered in the model immediately.

17.473.3 Member Function Documentation

17.473.3.1 _addSimulationControl()

```
void ModelDataDefinition::_addSimulationControl (
            SimulationControl * control )  [protected], [virtual]
```

Reimplemented in Buffer, PickStation, and Schedule.

17.473.3.2 _check()

```
bool ModelDataDefinition::_check (
            std::string & errorMessage )  [protected], [virtual]
```

could be overriden by derived classes

Reimplemented in Attribute, Counter, Entity, StatisticsCollector, SinkModelComponent, SourceModelComponent, AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState, GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent, DiffEquations, DiffusionSimulate, LSODE, OLD_ODEelement, Decide, DropOff, Remove, Search, Buffer, Clone, Delay, Process, Release, Seize, CppForG, PythonForG, RSimulator, Batch, Separate, Record, Write, Assign, Create, Dispose, Access, Enter, Exit, Leave, Move, PickStation, Route, Start, Stop, Store, Unstore, ModalModelDefault, Submodel, Match, Signal, Wait, BioStateProjectionComponent, CellCycleCheckpointComponent, CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CompartmentExchangeComponent, EukaryoticCellCycleComponent, FtsZPolymerizationComponent, MetabolicStateProjectionComponent, MetabolicSubmodelComponent, PathwayStressResponseComponent, ResourceAllocationComponent, StochasticReactionComponent, StochasticTranscription, StochasticTranslation, AISupport, BacteriaSignalGrid, BioNetwork, BioParameter, BioReaction, BioSimulatorRunner, BioSpecies, GeneticCircuit, GeneticCircuitPart, GeneticRegulation, GroProgram, MetabolicNetwork, MetabolicReaction, DiffusionField, ODESolver, Failure, Queue, Resource, Schedule, CppCompiler, OctaveRunner, PythonRuntime, RSimulatorRunner, SPICERunner, EntityGroup, File, Formula, Label, Set, Variable, Conveyor, Distance, Segment, Sequence, Station, Storage, Transporter, ColoredPetriNetNetwork, CPNArc, CPNTransition, DefaultNetwork, DirectedAcyclicGraphNetwork, EFSMNetwork, GraphEdge, GraphNetwork, MarkovChainNetwork, SignalData, DummyElement, BioCompartment, MolecularSpecies, StochasticReactionRule, and WholeCellState.

17.473.3.3 _createAttachedAttributes()

```
void ModelDataDefinition::_createAttachedAttributes ( )  [protected], [virtual]
```

Reimplemented in Formula.

17.473.3.4 _createEditableDataDefinitions()

```
void ModelDataDefinition::_createEditableDataDefinitions ( )  [protected], [virtual]
```

Reimplemented in DiffEquations, Remove, Search, RSimulator, Assign, and BioNetwork.

17.473.3.5 _createInternalAndAttachedData()

```
void ModelDataDefinition::_createInternalAndAttachedData ( )  [protected], [virtual]
```

Legacy compatibility hook. Prefer the granular create∗ methods and the composed association manager.

17.473.3.6 _createNonEditableDataDefinitions()

```
void ModelDataDefinition::_createNonEditableDataDefinitions ( )  [protected], [virtual]
```

Reimplemented in SPICECircuit, and CppForG.

17.473.3.7 _getParserChangesInformation()

```
ParserChangesInformation * ModelDataDefinition::_getParserChangesInformation ( )  [protected],
[virtual]
```

This method returns all changes in the parser that are needed by plugins of this ModelDatas. When connecting a new plugin, ParserChangesInformation are used to change parser source code, whch is after compiled and dinamically linked to to simulator kernel to reflect the changes

Reimplemented in Buffer, PickStation, Queue, Schedule, File, Set, and Storage.

17.473.3.8 _getSaveDefaultsOption()

```
bool ModelDataDefinition::_getSaveDefaultsOption ( )  [protected]
```

Returns a list of keys (names) of internal ModelDatas, cuch as Counters, StatisticsCollectors and others. Children↩ Elements are ModelDatas used by this ModelDataDefinition thar are needed before model checking

17.473.3.9 _initBetweenReplications()

```
void ModelDataDefinition::_initBetweenReplications ( )  [protected], [virtual]
```

Reimplemented in CppForG, and CellularAutomataComp.

17.473.3.10 _loadInstance()

```
bool ModelDataDefinition::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Implements PersistentObject_base.
Reimplemented in Attribute, Counter, Entity, EntityType, StatisticsCollector, ModelComponent, SinkModelComponent, SourceModelComponent, AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState, GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent, DiffEquations, DiffusionSimulate, LSODE, OLD_ODEelement, Decide, DropOff, Remove, Search, Buffer, Clone, Delay, Process, Release, Seize, SPICECircuit, Resistor, Vsource, Vpulse, Vsine, Capacitor, Diode, PMOS, NMOS, NOT, NAND, AND, NOR, OR, XOR, XNOR, SPICENode, CppForG, PythonForG, RSimulator, Batch, Separate, Record, Write, Assign, Create, Dispose, Access, Enter, Exit, Leave, Move, PickStation, Route, Start, Stop, Store, Unstore, CellularAutomataComp, DefaultNode, FSMState, ModalModelDefault, PetriPlace, Submodel, Match, Signal, Wait, DummyComponent, BioStateProjectionComponent, CellCycleCheckpointComponent, CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CompartmentExchangeComponent, EukaryoticCellCycleComponent, FtsZPolymerizationComponent, MetabolicStateProjectionComponent, MetabolicSubmodelCompone PathwayStressResponseComponent, ResourceAllocationComponent, StochasticReactionComponent, StochasticTranscription, StochasticTranslation, AISupport, BacteriaSignalGrid, BioNetwork, BioParameter, BioReaction, BioSimulatorRunner, BioSpecies, GeneticCircuit, GeneticCircuitPart, GeneticRegulation, GroProgram, MetabolicNetwork, MetabolicReaction, DiffusionField, ODESolver, Failure, Queue, Resource, Schedule, CppCompiler, OctaveRunner, PythonRuntime, RSimulatorRunner, SPICERunner, EntityGroup, File, Formula, Label, Set, Variable, Conveyor, Distance, Segment, Sequence, Station, Storage, Transporter, ColoredPetriNetNetwork, CPNArc, CPNTransition, DefaultNetwork, EFSMNetwork, GraphEdge, GraphNetwork, MarkovChainNetwork, SignalData, DummyElement, BioCompartment, MolecularSpecies, StochasticReactionRule, and WholeCellState.

17.473.3.11 _saveInstance()

```
void ModelDataDefinition::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Implements PersistentObject_base.
Reimplemented in Attribute, Counter, Entity, EntityType, StatisticsCollector, ModelComponent, SinkModelComponent, SourceModelComponent, AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState, GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent, DiffEquations, DiffusionSimulate, LSODE, OLD_ODEelement, Decide, DropOff, Remove, Search, Buffer, Clone, Delay, Process, Release, Seize, SPICECircuit, Resistor, Vsource, Vpulse, Vsine, Capacitor, Diode, PMOS, NMOS, NOT, NAND, AND, NOR, OR, XOR, XNOR, SPICENode, CppForG, PythonForG, RSimulator, Batch, Separate, Record, Write, Assign, Create, Dispose, Access, Enter, Exit, Leave, Move, PickStation, Route, Start, Stop, Store, Unstore, CellularAutomataComp, DefaultNode, FSMState, ModalModelDefault, PetriPlace, Submodel, Match, Signal, Wait, DummyComponent, BioStateProjectionComponent, CellCycleCheckpointComponent,

CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CompartmentExchangeComponent, EukaryoticCellCycleComponent, FtsZPolymerizationComponent, MetabolicStateProjectionComponent, MetabolicSubmodelCompone PathwayStressResponseComponent, ResourceAllocationComponent, StochasticReactionComponent, StochasticTranscription, StochasticTranslation, AISupport, BacteriaSignalGrid, BioNetwork, BioParameter, BioReaction, BioSimulatorRunner, BioSpecies, GeneticCircuit, GeneticCircuitPart, GeneticRegulation, GroProgram, MetabolicNetwork, MetabolicReaction, DiffusionField, ODESolver, Failure, Queue, Resource, Schedule, CppCompiler, OctaveRunner, PythonRuntime, RSimulatorRunner, SPICERunner, EntityGroup, File, Formula, Label, Set, Variable, Conveyor, Distance, Segment, Sequence, Station, Storage, Transporter, ColoredPetriNetNetwork, CPNArc, CPNTransition, DefaultNetwork, EFSMNetwork, GraphEdge, GraphNetwork, MarkovChainNetwork, SignalData, DummyElement, BioCompartment, MolecularSpecies, StochasticReactionRule, and WholeCellState.

17.473.3.12 Check()

```
bool ModelDataDefinition::Check (
            ModelDataDefinition * modeldatum,
            std::string & errorMessage )  [static]
```

Validates a data definition instance.
This helper invokes the instance _check() method to validate the object and any data it creates or references.

Parameters

modeldatum	Instance to validate.
errorMessage	Output error message when validation fails.

Returns

`true` when the instance is valid.

17.473.3.13 CreateInternalData()

```
void ModelDataDefinition::CreateInternalData (
            ModelDataDefinition * modeldatum )  [static]
```

Creates internal and attached data required by this instance.
This helper invokes the protected _check() path of the instance, which creates internal ModelDataDefinitions and other related data such as attributes or variables.

Parameters

modeldatum	Instance whose associated data should be created.

17.473.3.14 CreateRelatedDataElements()

```
bool ModelDataDefinition::CreateRelatedDataElements (
            ModelDataDefinition * modeldatum,
            std::string & errorMessage )  [static]
```

Creates related data and validates the instance in a single call.
Materializes related data and runs local checks for the instance in a single step.

Parameters

modeldatum	Instance whose related data should be materialized.
errorMessage	Output error message when validation fails.

Returns

`true` when creation and validation succeed.

17.473.3.15 defineTraceLevelSpecific()

```
void ModelDataDefinition::defineTraceLevelSpecific (
            TraceManager::Level traceLevelspecific,
            bool traceLevelSpecificEnabled = true )
```

Defines the specific trace level and optionally enables it immediately.

Parameters

traceLevelspecific	New trace level.
traceLevelSpecificEnabled	Whether the specific trace level starts enabled.

17.473.3.16 getAttachedData()

```
std::map< std::string, ModelDataDefinition * > * ModelDataDefinition::getAttachedData ( )
const
```

Returns the full map of attached data definitions.

Returns

Map of attached data indexed by name.

17.473.3.17 getClassname()

```
const std::string & ModelDataDefinition::getClassname ( ) const
```

Returns the runtime class name used by the plugin system.

Returns

Concrete class name.

17.473.3.18 getId()

```
Util::identification ModelDataDefinition::getId ( ) const
```

Returns the unique identifier of this instance.

Returns

Instance identifier.

17.473.3.19 getInternalData() [1/2]

```
std::map< std::string, ModelDataDefinition * > * ModelDataDefinition::getInternalData ( )
const
```

Returns the full map of internal child data definitions.

Returns

Map of internal children indexed by name.

17.473.3.20 getInternalData() [2/2]

```
ModelDataDefinition * ModelDataDefinition::getInternalData (
            const std::string & name ) const
```

Looks up a named internal child data definition.

Parameters

name	Child name to search for.

Returns

Matching internal child, or `nullptr` when not found.

17.473.3.21 getLabel()

`const std::string & ModelDataDefinition::getLabel ( ) const`
Returns the user-visible label of this instance.

Returns

Instance label.

17.473.3.22 getLevel()

`unsigned int ModelDataDefinition::getLevel ( ) const`
Returns the hierarchical editing context containing this element.
Zero denotes the root model view. A nonzero value identifies the ModelDataDefinition that owns the editing context; a ModelComponent may identify a context because it derives from ModelDataDefinition. Context membership does not transfer object ownership or imply Entity flow.

Returns

Current editing-context identifier (not an ordinal depth).

17.473.3.23 getName()

`const std::string & ModelDataDefinition::getName ( ) const`
Returns the logical name of this instance.

Returns

Instance name.

17.473.3.24 getParentModel()

`Model * ModelDataDefinition::getParentModel ( ) const`
Returns the parent model that owns this definition.

Returns

Parent model pointer, or `nullptr` when detached.

17.473.3.25 getSimulationControls()

`List< SimulationControl * > * ModelDataDefinition::getSimulationControls ( ) const`
Returns the simulation controls owned by this data definition.
Preferred API for writable controls owned by this model data definition.

Returns

Writable control list managed by the definition.

17.473.3.26 getTraceLevelSpecific()

```
TraceManager::Level ModelDataDefinition::getTraceLevelSpecific ( ) const
```

Returns the trace level that applies specifically to this definition.

Returns

Explicit trace level for this instance.

17.473.3.27 hasChanged()

```
bool ModelDataDefinition::hasChanged ( ) const
```

Indicates whether this instance has been modified since the last reset.

Returns

`true` when the object has pending changes.

17.473.3.28 InitBetweenReplications()

```
void ModelDataDefinition::InitBetweenReplications (
            ModelDataDefinition * modeldatum )  [static]
```

Resets simulation-time state between replications.

Parameters

modeldatum	Instance to reset.

17.473.3.29 isReportStatistics()

```
bool ModelDataDefinition::isReportStatistics ( ) const
```

Indicates whether this data definition contributes report statistics.

Returns

`true` when this definition emits simulation statistics.

17.473.3.30 isTraceLevelSpecificEnabled()

```
bool ModelDataDefinition::isTraceLevelSpecificEnabled ( ) const
```

Indicates whether the specific trace level is enabled.

Returns

`true` when the instance-specific trace level is active.

17.473.3.31 LoadInstance()

```
ModelDataDefinition * ModelDataDefinition::LoadInstance (
            Model * model,
            PersistenceRecord * fields,
            bool insertIntoModel )  [static]
```

Loads a model data definition instance from serialized fields.

This helper receives a map of fields read from a file or other source, creates the instance, and invokes its protected _loadInstance() method. The instance can be automatically inserted into the simulation model when requested.

Parameters

model	Parent model that will own the loaded instance.
fields	Serialized fields to deserialize.
insertIntoModel	If `true`, registers the loaded instance in the model.

Returns

Newly created instance when loading succeeds.

17.473.3.32 NewInstance()

```
ModelDataDefinition * ModelDataDefinition::NewInstance (
            Model * model,
            std::string name = "" )  [static]
```

Creates a new instance of a data definition using the plugin registry.
This helper invokes the constructor and returns a new instance that usually requires a cast to the correct subclass. It is used when plugins are connected through dynamically loaded libraries.

Parameters

model	Parent model that will own the instance.
name	Initial object name.

Returns

Newly created data definition instance.

17.473.3.33 SaveInstance()

```
void ModelDataDefinition::SaveInstance (
            PersistenceRecord * fields,
            ModelDataDefinition * modeldatum )  [static]
```

Serializes a data definition instance into a persistence record.
This helper calls the instance _saveInstance() method and returns a field map that can be saved to a file or other destination.

Parameters

fields	Output record that receives the serialized fields.
modeldatum	Instance to serialize.

17.473.3.34 setHasChanged()

```
void ModelDataDefinition::setHasChanged (
            bool hasChanged )
```

Updates the changed flag for this data definition.

Parameters

hasChanged	New changed-state value.

17.473.3.35 setLabel()

```
void ModelDataDefinition::setLabel (
            const std::string & label )
```

Updates the user-visible label of this instance.

Parameters

label	New label.

17.473.3.36 setModelLevel()

```
void ModelDataDefinition::setModelLevel (
            unsigned int _modelLevel )
```

Sets this element's hierarchical editing context.
Use zero for the root context, or the ID of the containing ModelDataDefinition / ModelComponent. This API only updates the context key: the caller remains responsible for domain ownership and persistence.

Parameters

_modelLevel	Editing-context identifier.

17.473.3.37 setName()

```
void ModelDataDefinition::setName (
            const std::string & name )
```

Updates the logical name of this instance.

Parameters

name	New name.

17.473.3.38 setReportStatistics()

```
void ModelDataDefinition::setReportStatistics (
            bool reportStatistics )
```

Enables or disables report-statistics generation for this definition.

Parameters

reportStatistics	New report-statistics flag.

17.473.3.39 setTraceLevelSpecific()

```
void ModelDataDefinition::setTraceLevelSpecific (
            TraceManager::Level level )
```

Updates the trace level used by this definition.

Parameters

level	New trace level.

17.473.3.40 setTraceLevelSpecificEnabled()

```
void ModelDataDefinition::setTraceLevelSpecificEnabled (
            bool traceLevelSpecificEnabled )
```

Enables or disables the specific trace level.

Parameters

traceLevelSpecificEnabled	New enabled-state value.

17.473.3.41 show()

```
std::string ModelDataDefinition::show ( )  [virtual]
```

Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented in Attribute, Counter, Entity, EntityType, StatisticsCollector, ModelComponent, SourceModelComponent, AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState, GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent, DiffEquations, DiffusionSimulate, LSODE, OLD_ODEelement, Decide, DropOff, Remove, Search, Buffer, Clone, Delay, Process, Release, Seize, SPICECircuit, SPICENode, CppForG, PythonForG, RSimulator, Batch, Separate, Record, Write, Assign, Create, Dispose, Access, Enter, Exit, Leave, Move, PickStation, Route, Start, Stop, Store, Unstore, CellularAutomataComp, DefaultNode, ModalModelDefault, Submodel, Match, Signal, Wait, DummyComponent, BioStateProjectionComponent, CellCycleCheckpointComponent, CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CompartmentExchangeComponent, EukaryoticCellCycleComponent, FtsZPolymerizationComponent, MetabolicStateProjectionComponent, MetabolicSubmodelComponent, PathwayStressResponseComponent, ResourceAllocationComponent, StochasticReactionComponent, StochasticTranscription, StochasticTranslation, AISupport, BacteriaSignalGrid, BioNetwork, BioParameter, BioReaction, BioSimulatorRunner, BioSpecies, GeneticCircuit, GeneticCircuitPart, GeneticRegulation, GroProgram, MetabolicNetwork, MetabolicReaction, DiffusionField, ODESolver, Failure, Queue, Resource, Schedule, CppCompiler, OctaveRunner, PythonRuntime, RSimulatorRunner, SPICERunner, EntityGroup, File, Formula, Label, Set, Variable, Conveyor, Distance, Segment, Sequence, Station, Storage, Transporter, ColoredPetriNetNetwork, CPNArc, CPNTransition, DefaultNetwork, EFSMNetwork, GraphEdge, GraphNetwork, MarkovChainNetwork, SignalData, DummyElement, BioCompartment, MolecularSpecies, StochasticReactionRule, and WholeCellState.

17.473.3.42 traceSimulation()

```
void ModelDataDefinition::traceSimulation (
            void * thisobject,
            const std::string & text,
            TraceManager::Level level = TraceManager::Level::L8_detailed )  [protected]
```

Traces text to the simulation output.
Used only while a simulation is running, for example when components or data elements need to inform something.

Parameters

thisobject	Caller object used for trace attribution.
text	Trace text to emit.
level	Trace severity level.

17.474.1 Detailed Description

Owns the internal/attached registries and the new lifecycle buckets for a ModelDataDefinition.
The class starts as a compatibility layer around the current internal/attached storage so the kernel can move bucket by bucket without breaking direct callers that still inspect the legacy aggregate maps.
The documentation for this class was generated from the following files:

- kernel/simulator/model/ModelDataDefinitionAssociations.h
- kernel/simulator/model/ModelDataDefinitionAssociations.cpp

17.475 ModelDataManager Class Reference

Central registry for `ModelDataDefinition` instances owned by a model.
`#include <kernel/simulator/model/ModelDataManager.h>`

Public Member Functions

- **ModelDataManager** (Model *model)

  Creates a data manager attached to `model`.

  getDataDefinitionClassnames
- List< ModelDataDefinition * > * **getDataDefinitionList** (std::string datadefinitionTypename) const
- void **show** ()

  Prints a textual summary of registered model data definitions.
- Model * **getParentModel** () const

  Returns the model that owns this data manager.
- bool **hasChanged** () const

  Indicates whether managed data collections were modified.
- void **setHasChanged** (bool _hasChanged)

  Updates the internal changed flag.

17.475.1 Detailed Description

Central registry for `ModelDataDefinition` instances owned by a model.
This manager groups model data by typename, supports insertion/removal/lookup operations and offers consistency checks used by components and model validation.

17.475.2 Member Function Documentation

17.475.2.1 check() [1/2]

```
bool ModelDataManager::check (
            std::string datadefinitionTypename,
            ModelDataDefinition * anElement,
            std::string expressionName,
            std::string & errorMessage )
```

check

Parameters

datadefinitionTypename	
anElement	
expressionName	
errorMessage	

Returns

17.475.2.2 check() [2/2]

```
bool ModelDataManager::check (
            std::string datadefinitionTypename,
            std::string elementName,
            std::string expressionName,
            bool mandatory,
            std::string & errorMessage )
```

check

Parameters

datadefinitionTypename	
elementName	
expressionName	
mandatory	
errorMessage	

Returns

17.475.2.3 getDataDefinition() [1/2]

```
ModelDataDefinition * ModelDataManager::getDataDefinition (
            std::string datadefinitionTypename,
            std::string name )
```

getDataDefinition

Parameters

datadefinitionTypename	
name	

Returns

17.475.2.4 getDataDefinition() [2/2]

```
ModelDataDefinition * ModelDataManager::getDataDefinition (
            std::string datadefinitionTypename,
            Util::identification id )
```

getDataDefinition

Parameters

datadefinitionTypename	
id	

Returns

17.475.2.5 getDataDefinitionClassnames()

```
std::list< std::string > ModelDataManager::getDataDefinitionClassnames ( ) const
```

getDataDefinitionClassnames

Returns

Snapshot list of current data-definition class names returned by value.

17.475.2.6 getNumberOfDataDefinitions() [1/2]

```
unsigned int ModelDataManager::getNumberOfDataDefinitions ( )
```

getNumberOfDataDefinitions

Returns

17.475.2.7 getNumberOfDataDefinitions() [2/2]

```
unsigned int ModelDataManager::getNumberOfDataDefinitions (
            std::string datadefinitionTypename )
```

getNumberOfDataDefinitions

Parameters

datadefinitionTypename	

Returns

17.475.2.8 getRankOf()

```
int ModelDataManager::getRankOf (
            std::string datadefinitionTypename,
            std::string name )
```

getRankOf

Parameters

datadefinitionTypename	
name	

Returns

returns the position (1st position=0) of the modeldatum if found, or negative value if not found

17.475.2.9 insert() [1/2]

```
bool ModelDataManager::insert (
            ModelDataDefinition * anElement )
```

insert

Parameters

anElement	

Returns

17.475.2.10 insert() [2/2]

```
bool ModelDataManager::insert (
            std::string datadefinitionTypename,
            ModelDataDefinition * anElement )
```

insert

Parameters

datadefinitionTypename	
anElement	

Returns

Deprected

17.475.2.11 remove() [1/2]

```
void ModelDataManager::remove (
            ModelDataDefinition * anElement )
```

remove

Parameters

anElement	Deprected

17.475.2.12 remove() [2/2]

```
void ModelDataManager::remove (
            std::string datadefinitionTypename,
            ModelDataDefinition * anElement )
```

remove

Parameters

datadefinitionTypename	
anElement	

The documentation for this class was generated from the following files:

17.476 ModelEvent Class Reference

`#include <kernel/simulator/OnEventManager.h>`

Public Member Functions

- **ModelEvent** (Model *model)
- const Model * **getModel** ()

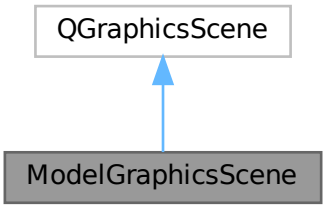
17.476.1 Detailed Description

Stores an event that happened on a specific model
The documentation for this class was generated from the following file:

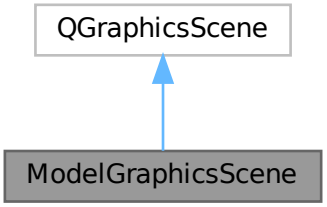
- kernel/simulator/OnEventManager.h

17.477 ModelGraphicsScene Class Reference

Scene that owns and manipulates the graphical representation of a model.
`#include <applications/gui/genesys/graphicals/ModelGraphicsScene.h>`
Inheritance diagram for ModelGraphicsScene:



Collaboration diagram for ModelGraphicsScene:



Classes

- struct GRID

Public Types

- enum **DrawingMode** {
  NONE , **LINE** , **TEXT** , **RECTANGLE** ,
  ELLIPSE , **POLYGON** , **POLYGON_POINTS** , **POLYGON_FINISHED** ,
  COUNTER , **VARIABLE** , **TIMER** , **ATTRIBUTE** ,
  ENTITY , **EVENT** , **EXPRESSION** , **PLOT** ,
  QUEUE_PLACEHOLDER , **RESOURCE** , **STATION** , **STATISTICS** }

Public Member Functions

- **ModelGraphicsScene** (qreal x, qreal y, qreal width, qreal height, QObject *parent=nullptr)
- **ModelGraphicsScene** (const ModelGraphicsScene &orig)=delete
- ModelGraphicsScene & **operator=** (const ModelGraphicsScene &other)=delete
- void **clear** ()

  Clears the scene and all formal-network projection bookkeeping.
- GraphicalModelComponent * **addGraphicalModelComponent** (Plugin *plugin, ModelComponent *component, QPointF position, QColor color=Qt::blue, bool notify=false, GraphicalModelComponent *autoConnectSource=nullptr)

  Creates and inserts one graphical component into the scene.
- GraphicalConnection * **addGraphicalConnection** (GraphicalComponentPort *sourcePort, GraphicalComponentPort *destinationPort, unsigned int portSourceConnection, unsigned int portDestinationConnection, bool notify=false)

  Creates and inserts one graphical connection between two ports.
- GraphicalModelDataDefinition * **addGraphicalModelDataDefinition** (Plugin *plugin, ModelDataDefinition *element, QPointF position, QColor color=Qt::blue)

  Creates and inserts one graphical data definition into the scene.
- GraphicalDiagramConnection * **addGraphicalDiagramConnection** (QGraphicsItem *dataDefinition, QGraphicsItem *linkedTo, GraphicalDiagramConnection::ConnectionType type)

  Creates or updates a diagram-level connection between data definitions.
- void **initializeAnimationDrawing** (QGraphicsSceneMouseEvent *mouseEvent)

  Starts the interactive drawing workflow for animation-related items.
- void **continueAnimationDrawing** (QGraphicsSceneMouseEvent *mouseEvent)

  Continues the interactive drawing workflow.
- void **finishAnimationDrawing** (QGraphicsSceneMouseEvent *mouseEvent)

Finalizes the interactive drawing workflow.

- void **startTextEditing** ()

  Opens inline text editing for the current text item.

- void **removeComponent** (GraphicalModelComponent ∗gmc, bool notify=false)

  Removes one component and optionally emits the graphical change notification.

- void **clearConnectionsComponent** (GraphicalModelComponent ∗gmc)

  Clears input and output connections attached to one component.

- void **clearInputConnectionsComponent** (GraphicalModelComponent ∗graphicalComponent)

  Removes all incoming connections from one component.

- void **clearOutputConnectionsComponent** (GraphicalModelComponent ∗graphicalComponent)

  Removes all outgoing connections from one component.

- void **clearPorts** (GraphicalConnection ∗connection, GraphicalModelComponent ∗source, GraphicalModelComponent ∗destination)

  Clears the connection ports associated with one connection before removal.

- void **connectComponents** (GraphicalConnection ∗connection, GraphicalModelComponent ∗source=nullptr, GraphicalModelComponent ∗destination=nullptr, bool notify=false)

  Connects one prepared connection to its source and destination items.

- bool **connectSource** (GraphicalConnection ∗connection, GraphicalModelComponent ∗source=nullptr)

  Binds a source component to a connection while checking port constraints.

- bool **connectDestination** (GraphicalConnection ∗connection, GraphicalModelComponent ∗destination=nullptr)

  Binds a destination component to a connection while checking port constraints.

- void **redoConnections** (GraphicalModelComponent ∗graphicalComponent, QList< GraphicalConnection ∗ > ∗inputConnections, QList< GraphicalConnection ∗ > ∗outputConnections)

  Recreates all connection links for one graphical component.

- void **removeComponentInModel** (GraphicalModelComponent ∗gmc)

  Removes one component from the kernel model as part of scene deletion.

- void **insertComponent** (GraphicalModelComponent ∗gmc, QList< GraphicalConnection ∗ > ∗input↩ Connections, QList< GraphicalConnection ∗ > ∗outputConnections, bool addGMC=true, bool addAll↩ GMC=true, bool notify=false)

  Inserts an existing component back into the scene and restores its connections.

- void **removeGraphicalConnection** (GraphicalConnection ∗graphicalConnection, GraphicalModelComponent ∗source, GraphicalModelComponent ∗destination, bool notify=false)

  Removes a graphical connection and updates the source/destination items.

- void **removeConnectionInModel** (GraphicalConnection ∗graphicalConnection, GraphicalModelComponent ∗source)

  Removes the connection from the kernel model while keeping scene state consistent.

- void **addGeometry** (QPointF endPoint, bool moving)

  Adds one freeform drawing geometry item to the scene.

- void **addDrawing** (QGraphicsItem ∗item, bool notify=false)

  Adds one drawing item to the scene and optionally notifies listeners.

- bool **addDrawingGeometry** (QGraphicsItem ∗item)

  Attempts to register one geometry drawing item.

- bool **addDrawingAnimation** (QGraphicsItem ∗item)

  Attempts to register one animation drawing item.

- void **removeGraphicalModelDataDefinition** (GraphicalModelDataDefinition ∗gmdd)

  Removes one graphical data definition from the scene.

- void **detachGraphicalModelDataDefinition** (GraphicalModelDataDefinition ∗gmdd)

  Detaches one graphical data definition without deleting the underlying model data.

- void **restoreGraphicalModelDataDefinition** (GraphicalModelDataDefinition ∗gmdd)

  Restores one previously detached graphical data definition.

- void **removeGraphicalDiagramConnection** (GraphicalDiagramConnection ∗connection)

  Removes one diagram connection from the scene.

- void **clearGraphicalModelDataDefinitions** ()

  Clears all graphical data definitions from the scene.
- void **clearGraphicalDiagramConnections** ()

  Clears all diagram connections from the scene.
- void **sanitizeGraphicalDataDefinitionsBookkeeping** ()

  Repairs bookkeeping used to track graphical data definitions.
- void **setDiagramLayerState** (bool diagramCreated, bool visible)

  Shows or hides the diagram layer and its creation state.
- QList< QGraphicsItem * > **userOperableItems** (const QList< QGraphicsItem * > &items) const

  Filters out scene items that the user cannot directly manipulate.
- QList< QGraphicsItem * > **userDeletableItems** (const QList< QGraphicsItem * > &items) const

  Filters the selected items down to items that can be deleted.
- void **ensureInitialInternalDataDefinitionGrouping** (GraphicalModelDataDefinition *dataDefinition, GraphicalModelComponent *component)

  Optionally groups newly created internal data definitions under their component.
- void **setPersistedGuiRestoreInProgress** (bool restoring)

  Marks that persisted GUI state is being restored.
- bool **isPersistedGuiRestoreInProgress** () const

  Returns whether persisted GUI state restoration is in progress.
- void **removeDrawing** (QGraphicsItem *item, bool notify=false)

  Removes one freeform drawing item from the scene.
- bool **removeDrawingGeometry** (QGraphicsItem *item)
- bool **removeDrawingAnimation** (QGraphicsItem *item)
- void **removeGroup** (QGraphicsItemGroup *group, bool notify=false)

  Removes one graphical group item from the scene.
- void **clearGraphicalModelComponents** ()

  Clears all graphical component items from the scene.
- void **clearGraphicalModelConnections** ()

  Clears all graphical connection items from the scene.
- void **groupComponents** (bool notify=false)

  Groups the current selection into a scene group when possible.
- void **groupModelComponents** (QList< GraphicalModelComponent * > *graphicalComponents, QGraphicsItemGroup *group)

  Groups the supplied graphical components into the provided group item.
- void **ungroupComponents** (bool notify=false)

  Ungroups the current selection when it contains a valid group item.
- void **ungroupModelComponents** (QGraphicsItemGroup *group)

  Ungroups one group item and restores its child components.
- void notifyGraphicalModelChange (GraphicalModelEvent::EventType eventType, GraphicalModelEvent::↩ EventObjectType eventObjectType, QGraphicsItem *item)

  Emits a scene-level change notification used by higher GUI layers.
- QList< GraphicalModelComponent * > **graphicalModelComponentItems** ()

  Returns the list of graphical component items currently in the scene.
- GraphicalModelComponent * **findGraphicalModelComponent** (Util::identification id)

  Finds one graphical component by kernel identification.
- GraphicalModelDataDefinition * **findGraphicalModelDataDefinition** (ModelDataDefinition *dataDefinition)

  Finds one graphical data definition by kernel pointer.
- void **clearEFSMNetworkDiagramItems** ()

  Removes all read-only EFSM transition graphics from this scene.
- void **addEFSMNetworkDiagramItem** (QGraphicsItem *item)

  Adds one scene-owned read-only EFSM transition graphic.

- QList< QGraphicsItem * > * **getEFSMNetworkDiagramItems** () const

  Returns the scene-owned EFSM transition graphics.
- GraphicalModelComponent * **resolveSourceComponent** (GraphicalConnection *connection) const

  Resolves the source component associated with one graphical connection.
- GraphicalModelComponent * **resolveDestinationComponent** (GraphicalConnection *connection) const

  Resolves the destination component associated with one graphical connection.
- GRID * **grid** ()

  Returns the current grid state owned by the scene.
- void **showGrid** ()

  Shows the grid using the current grid configuration.
- void **setGridVisible** (bool visible)

  Sets grid visibility without toggling the state implicitly.
- bool **isGridVisible** () const

  Returns whether the grid is currently visible.
- void **snapItemsToGrid** ()

  Snaps movable items to the active grid spacing.
- void **actualizeDiagramArrows** ()

  Recomputes the direction arrows used by diagram connections.
- void **showDiagrams** ()

  Shows all diagram-layer items.
- void **hideDiagrams** ()

  Hides all diagram-layer items.
- bool **existDiagram** ()

  Returns whether diagram-layer items exist.
- bool **visibleDiagram** ()

  Returns whether diagram-layer items are currently visible.
- void **destroyDiagram** ()

  Destroys the diagram layer and its cached items.
- void **createDiagrams** ()

  Creates the diagram layer and its cached items.
- QUndoStack * **getUndoStack** ()

  Returns the undo stack used by the scene.
- Simulator * **getSimulator** ()

  Returns the simulator bound to this scene.
- void **setUndoStack** (QUndoStack *undo)

  Replaces the undo stack used by the scene.
- void **beginConnection** ()

  Starts a new component connection gesture.
- void **setSimulator** (Simulator *simulator)

  Sets the simulator dependency used by scene logic.
- void **setPropertyEditor** (PropertyEditorGenesys *propEditor)

  Sets the property editor dependency used by scene logic.
- void **setPropertyList** (std::map< SimulationControl *, DataComponentProperty * > *propList)

  Sets the property list dependency used by scene logic.
- void **setPropertyEditorUI** (std::map< SimulationControl *, DataComponentEditor * > *propEditorUI)

  Sets the property-editor widget map used by scene logic.
- void **setComboBox** (std::map< SimulationControl *, ComboBoxEnum * > *propCombo)

  Sets the enum combo-box map used by scene logic.
- void **setObjectBeingDragged** (QTreeWidgetItem *objectBeingDragged)

  Records which tree item is currently being dragged into the scene.
- void **setRestoringPersistedGuiLayout** (bool restoring)

Marks whether the scene is restoring persisted GUI layout.

- bool **isRestoringPersistedGuiLayout** () const

  Returns whether the scene is restoring persisted GUI layout.

- void **setParentWidget** (QWidget *parentWidget)

  Sets the parent widget used by transient UI interactions.

- unsigned short **connectingStep** () const

  Returns the current step in the connection gesture.

- void **setConnectingStep** (unsigned short connectingStep)

  Updates the current step in the connection gesture.

- void **setSnapToGrid** (bool activated)

  Enables or disables grid snapping.

- bool **getSnapToGrid** ()

  Returns whether grid snapping is enabled.

- void **arranjeModels** (int direction)

  Rearranges model items using the specified layout direction.

- void **setDrawingMode** (DrawingMode drawingMode)

  Sets the current drawing mode used by mouse gestures.

- void **clearDrawingMode** ()

  Clears the current drawing mode.

- void **setGraphicalComponentPort** (GraphicalComponentPort *in)

  Sets the current port used by connection gestures.

- DrawingMode **getDrawingMode** ()

  Returns the current drawing mode.

- void **setAction** (QAction *action)

  Sets the QAction that tracks the current scene tool.

- QList< GraphicalModelComponent * > * **getAllComponents** ()

  Returns all component items owned by the scene.

- QList< GraphicalConnection * > * **getAllConnections** ()

  Returns all connection items owned by the scene.

- QList< GraphicalModelDataDefinition * > * **getAllDataDefinitions** ()

  Returns all data-definition items owned by the scene.

- QList< GraphicalDiagramConnection * > * **getAllGraphicalDiagramsConnections** ()

  Returns all diagram-connection items owned by the scene.

- QMap< QGraphicsItemGroup *, QList< GraphicalModelComponent * > > **getListComponentsGroup** ()

  Returns the mapping used to restore grouped components.

- void **insertComponentGroup** (QGraphicsItemGroup *group, QList< GraphicalModelComponent * > componentsGroup)

  Stores the component list associated with one graphical group.

- void **insertOldPositionItem** (QGraphicsItem *item, QPointF position)

  Stores the previous scene position for one item.

- QPointF **getOldPositionItem** (QGraphicsItem *item) const

  Returns the previous scene position stored for one item.

- QList< AnimationTransition * > * **getAnimationsTransition** ()

  Returns the active transition animations tracked by the scene.

- QList< AnimationCounter * > * **getAnimationsCounter** ()

  Returns the active counter animations tracked by the scene.

- QList< AnimationVariable * > * **getAnimationsVariable** ()

  Returns the active variable animations tracked by the scene.

- QList< AnimationTimer * > * **getAnimationsTimer** ()

  Returns the active timer animations tracked by the scene.

- QList< AnimationPlaceholder * > * **getAnimationsPlaceholder** ()

Returns the placeholder animation items tracked by the scene.

- QMap< Event *, QList< AnimationTransition * > * > * **getAnimationPaused** ()

  Returns paused animations indexed by their simulation event.
- bool **checkIgnoreEvent** ()

  Returns true when the scene should suppress animation-driven event handling.
- void **clearAnimations** ()

  Clears all animation categories tracked by the scene.
- void **clearAnimationsTransition** ()

  Clears transition animations tracked by the scene.
- void **clearAnimationsCounter** ()

  Clears counter animations tracked by the scene.
- void **clearAnimationsVariable** ()

  Clears variable animations tracked by the scene.
- void **clearAnimationsTimer** ()

  Clears timer animations tracked by the scene.
- void **clearAnimationsPlaceholder** ()

  Clears placeholder animations tracked by the scene.
- void **clearAnimationsQueue** ()

  Clears queue animation overlays tracked by the scene.
- void **animatePlot** ()

  Refreshes plot animation overlays for the current scene state.
- QList< QString > * **getImagesAnimation** ()

  Returns the list of animation image identifiers used by the scene.
- void **drawingCounter** ()

  Creates counter overlay geometry.
- void **drawingVariable** ()

  Creates variable overlay geometry.
- void **drawingTimer** ()

  Creates timer overlay geometry.
- void **drawingAttribute** ()

  Creates attribute overlay geometry.
- void **drawingEntity** ()

  Creates entity overlay geometry.
- void **drawingEvent** ()

  Creates event overlay geometry.
- void **drawingExpression** ()

  Creates expression overlay geometry.
- void **drawingPlot** ()

  Creates plot overlay geometry.
- void **drawingQueue** ()

  Creates queue overlay geometry.
- void **drawingResource** ()

  Creates resource overlay geometry.
- void **drawingStation** ()

  Creates station overlay geometry.
- void **drawingStatistics** ()

  Creates statistics overlay geometry.
- void **clearAnimationsValues** ()

  Clears animation-specific cached values.
- void **setCounters** ()

  Synchronizes the component counters used by animation overlays.

- void **setVariables** ()

  Synchronizes the variable counters used by animation overlays.
- void **insertRestoredDataDefinitions** (bool loaded)

  Restores data definitions removed by previous delete/check cycles.
- void **saveDataDefinitions** ()

  Caches data definitions before destructive scene operations.
- void **requestGraphicalDataDefinitionsSync** ()

  Requests an immediate data-definition synchronization pass.
- void **scheduleGraphicalDataDefinitionsSync** ()

  Schedules a deferred data-definition synchronization pass.
- bool **isGraphicalDataDefinitionsSyncInProgress** () const

  Returns whether a data-definition sync is currently in progress.
- void **setShowStatisticsDataDefinitions** (bool show)

  Shows or hides statistics-related data definitions.
- bool **showStatisticsDataDefinitions** () const

  Returns whether statistics-related data definitions are visible.
- void **setShowEditableDataDefinitions** (bool show)

  Shows or hides editable data definitions.
- bool **showEditableDataDefinitions** () const

  Returns whether editable data definitions are visible.
- void **setShowSharedDataDefinitions** (bool show)

  Shows or hides shared data definitions.
- bool **showSharedDataDefinitions** () const

  Returns whether shared data definitions are visible.
- void **setShowRecursiveDataDefinitions** (bool show)

  Shows or hides recursive data-definition expansion.
- bool **showRecursiveDataDefinitions** () const

  Returns whether recursive data-definition expansion is enabled.
- void setModelLevelFilter (unsigned int modelLevel)

  Restricts graphical rebuild/synchronization services to one kernel model level.
- void **clearModelLevelFilter** ()

  Clears any level restriction and lets rebuild services render all model levels.
- bool **hasModelLevelFilter** () const

  Returns true when this scene is scoped to a specific ModelDataDefinition level.
- unsigned int **modelLevelFilter** () const

  Returns the active level used by rebuild services when the filter is enabled.
- void **setShowInternalDataDefinitions** (bool show)

  Shows or hides internal data definitions.
- bool **showInternalDataDefinitions** () const

  Returns whether internal data definitions are visible.
- void **setShowAttachedDataDefinitions** (bool show)

  Shows or hides attached data definitions.
- bool **showAttachedDataDefinitions** () const

  Returns whether attached data definitions are visible.
- void **setConnectionGeometryUpdatesBlocked** (bool blocked)

  Temporarily blocks connection-geometry updates.
- bool **areConnectionGeometryUpdatesBlocked** () const

  Returns whether connection-geometry updates are blocked.
- QList< QGraphicsItem * > * **getGraphicalModelDataDefinitions** () const

  Returns the scene items classified as model data definitions.
- QList< QGraphicsItem * > * **getGraphicalModelComponents** () const

Returns the scene items classified as model components.

- QList< QGraphicsItem * > * **getGraphicalConnections** () const

  Returns the scene items classified as connections.

- QList< QGraphicsItem * > * **getGraphicalGeometries** () const

  Returns the scene items classified as geometry drawings.

- QList< QGraphicsItem * > * **getGraphicalAnimations** () const

  Returns the scene items classified as animations.

- QList< QGraphicsItem * > * **getGraphicalEntities** () const

  Returns the scene items classified as entities.

- QList< QGraphicsItem * > * **getGraphicalDiagramsConnections** () const

  Returns the scene items classified as diagram connections.

- QList< QGraphicsItemGroup * > * **getGraphicalGroups** () const

  Returns the groups currently tracked by the scene.

- void **animateTransition** (ModelComponent *source, ModelComponent *destination, bool viewSimulation, Event *event)

  Starts a transition animation between two model components.

- void **runAnimateTransition** (AnimationTransition *animationTransition, Event *event, bool restart=false)

  Runs one transition animation instance until completion.

- void **handleAnimationStateChanged** (QAbstractAnimation::State newState, QEventLoop *loop, Event *event, AnimationTransition *animationTransition)

  Handles animation state changes for transition-driven event loops.

- void **animateQueueInsert** (ModelComponent *component, bool visivible)

  Creates the queue-insert animation overlay for one component.

- void **animateQueueRemove** (ModelComponent *component)

  Creates the queue-remove animation overlay for one component.

- void **animateCounter** ()

  Updates the counter animation overlay.

- void **animateVariable** (Entity *entity=nullptr)

  Updates the variable animation overlay.

- void **animateTimer** (double time)

  Updates the timer animation overlay.

Protected Member Functions

- virtual void **contextMenuEvent** (QGraphicsSceneContextMenuEvent *contextMenuEvent)
- virtual void **dragEnterEvent** (QGraphicsSceneDragDropEvent *event)
- virtual void **dragLeaveEvent** (QGraphicsSceneDragDropEvent *event)

- virtual void **wheelEvent** (QGraphicsSceneWheelEvent *wheelEvent)

17.477.1 Detailed Description

Scene that owns and manipulates the graphical representation of a model.
The scene manages components, ports, connections, drawings, animations, and the auxiliary data-definition structures used by the GUI. It is the central editing surface for the graphical model and the main consumer of the view/controller services documented elsewhere.

17.477.2 Member Function Documentation

17.477.2.1 notifyGraphicalModelChange()

```
void ModelGraphicsScene::notifyGraphicalModelChange (
            GraphicalModelEvent::EventType eventType,
            GraphicalModelEvent::EventObjectType eventObjectType,
            QGraphicsItem * item )
```

Emits a scene-level change notification used by higher GUI layers.
Notifies view-level handlers about changes in graphical model.
Event object is stack-allocated and forwarded by const-reference to avoid heap ownership ambiguity.

Todo Consider broadcasting to all attached views when multi-view editing is supported.

17.477.2.2 setModelLevelFilter()

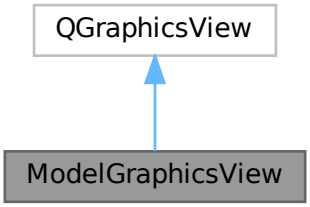
```
void ModelGraphicsScene::setModelLevelFilter (
            unsigned int modelLevel )
```

Restricts graphical rebuild/synchronization services to one kernel model level.
ModelGraphicsScene keeps this rendering context because some synchronization entry points are static services called from the property editor. Storing the active level in the scene lets those calls preserve the same root/submodel scope as the visible tab.
The documentation for this class was generated from the following files:

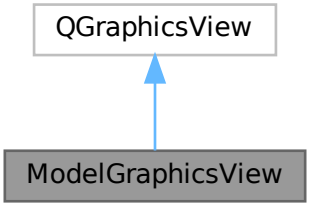
- applications/gui/genesys/graphicals/ModelGraphicsScene.h
- applications/gui/genesys/graphicals/ModelGraphicsScene.cpp

17.478 ModelGraphicsView Class Reference

Inheritance diagram for ModelGraphicsView:



Collaboration diagram for ModelGraphicsView:



Public Member Functions

- ModelGraphicsView (QWidget *parent=nullptr)

  View wrapper that hosts the model graphics scene and delegates GUI events.
- **ModelGraphicsView** (const ModelGraphicsView &orig)

  Copy constructor used by legacy compatibility paths.
- virtual ~**ModelGraphicsView** ()

  Releases the Qt view and its compatibility state.
- ModelGraphicsScene * **getScene** ()

  Returns the scene currently owned by the view.
- void **showGrid** ()

  Requests grid visibility from the underlying scene.
- void **clear** ()

  Clears the current scene contents and compatibility state.
- void **beginConnection** ()

  Starts the connection-creation workflow in the scene.
- void **selectModelComponent** (ModelComponent *component)

  Highlights the requested component in the scene and centers it when possible.
- void **setSimulator** (Simulator *simulator)

  Injects the simulator dependency used by scene callbacks.
- void **setPropertyEditor** (PropertyEditorGenesys *propEditor)

  Injects the property editor dependency used by scene callbacks.
- void **setPropertyList** (std::map< SimulationControl *, DataComponentProperty * > *propList)

  Injects the property list map used by scene/editor synchronization.
- void **setPropertyEditorUI** (std::map< SimulationControl *, DataComponentEditor * > *propEditorUI)

  Injects the property-editor widget map used by scene/editor synchronization.
- void **setComboBox** (std::map< SimulationControl *, ComboBoxEnum * > *propBox)

  Injects the enum combo-box map used by scene/editor synchronization.
- void **setEnabled** (bool enabled)

  Enables or disables interaction while keeping the scene wiring intact.
- QList< QGraphicsItem * > **selectedItems** ()

  Returns the current selected items from the underlying scene.
- template<typename Class >
  void **setSceneMouseEventHandler** (Class *object, void(Class::*function)(QGraphicsSceneMouseEvent *))
- template<typename Class >
  void **setGraphicalModelEventHandler** (Class *object, void(Class::*function)(const GraphicalModelEvent &))

- template<typename Class >
  void **setSceneWheelInEventHandler** (Class *object, void(Class::*function)())
- template<typename Class >
  void **setSceneWheelOutEventHandler** (Class *object, void(Class::*function)())
- template<typename Class >
  void **setContextMenuEventHandler** (Class *object, void(Class::*function)(QContextMenuEvent *))
- void **notifySceneMouseEventHandler** (QGraphicsSceneMouseEvent *mouseEvent)

  Notifies the registered mouse-event handler, if any.
- void **notifySceneWheelInEventHandler** ()

  Notifies the registered wheel-in handler, if any.
- void **notifySceneWheelOutEventHandler** ()

  Notifies the registered wheel-out handler, if any.
- void notifySceneGraphicalModelEventHandler (const GraphicalModelEvent &modelGraphicsEvent)

  Notifies the registered graphical-model-event handler, if any.
- void **setCanNotifyGraphicalModelEventHandlers** (bool can)

  Enables or disables graphical-model event emission from the view.
- void **clearEventHandlers** ()

  Clears all custom event handlers installed by the composition root.
- void **setParentWidget** (QWidget *parentWidget)

  Sets the widget used as parent for dialogs and transient controls.
- void **setRuleVisible** (bool visible)

  Enables or disables ruler rendering over the graphics viewport.
- bool **isRuleVisible** () const

  Returns whether ruler rendering is active.
- void **setGuidesVisible** (bool visible)

  Enables or disables guide line rendering over the graphics viewport.
- bool **isGuidesVisible** () const

  Returns whether guide line rendering is active.

Protected Member Functions

- void **changed** (const QList< QRectF > &region)
- void **focusItemChanged** (QGraphicsItem *newFocusItem, QGraphicsItem *oldFocusItem, Qt::FocusReason reason)
- void **sceneRectChanged** (const QRectF &rect)
- void **selectionChanged** ()
- virtual void **contextMenuEvent** (QContextMenuEvent *event) override
- virtual void **dragEnterEvent** (QDragEnterEvent *event) override
- virtual void **keyPressEvent** (QKeyEvent *event) override
- virtual void **keyReleaseEvent** (QKeyEvent *event) override
- virtual void **wheelEvent** (QWheelEvent *event) override
- virtual void **drawForeground** (QPainter *painter, const QRectF &rect) override

17.478.1 Constructor & Destructor Documentation

17.478.1.1 ModelGraphicsView()

```
ModelGraphicsView::ModelGraphicsView (
            QWidget * parent = nullptr )
```

View wrapper that hosts the model graphics scene and delegates GUI events.
The view keeps the scene-specific input handlers outside the raw Qt widget layer so the MainWindow composition root can wire context menus, wheel behavior, and selection changes through injected callbacks.

17.478.2 Member Function Documentation

17.478.2.1 notifySceneGraphicalModelEventHandler()

```
void ModelGraphicsView::notifySceneGraphicalModelEventHandler (
            const GraphicalModelEvent & modelGraphicsEvent )
```

Notifies the registered graphical-model-event handler, if any.
Dispatches graphical model change event to registered callback.

Parameters

modelGraphicsEvent	Event payload from scene.

Todo Replace callback with signal/slot to improve composability.

Todo actualize property editor?

- void saveInstance (PersistenceRecord *fields)

  saveInstance
- bool hasChanged () const

  hasChanged
- void **setHasChanged** (bool hasChanged)

  Updates the changed flag for model metadata.

17.480.1 Detailed Description

ModelInfo stores basic model project information, such as the project and analyst names.

17.480.2 Member Function Documentation

17.480.2.1 getAnalystName()

`std::string ModelInfo::getAnalystName ( ) const`

getAnalystName

Returns

17.480.2.2 getDescription()

```
std::string ModelInfo::getDescription ( ) const
```

getDescription

Returns

17.480.2.3 getName()

```
std::string ModelInfo::getName ( ) const
```

getName

Returns

17.480.2.4 getProjectTitle()

```
std::string ModelInfo::getProjectTitle ( ) const
```

getProjectTitle

Returns

17.480.2.5 getVersion()

```
std::string ModelInfo::getVersion ( ) const
```

getVersion

Returns

17.480.2.6 hasChanged()

```
bool ModelInfo::hasChanged ( ) const
```

hasChanged

Returns

17.480.2.7 loadInstance()

```
void ModelInfo::loadInstance (
            PersistenceRecord * fields )
```

loadInstance

Parameters

fields	

17.480.2.8 saveInstance()

```
void ModelInfo::saveInstance (
            PersistenceRecord * fields )
```

saveInstance

Parameters

fields	

17.480.2.9 setAnalystName()

```
void ModelInfo::setAnalystName (
            std::string _analystName )
```

setAnalystName

Parameters

_analystName	

17.480.2.10 setDescription()

```
void ModelInfo::setDescription (
            std::string _description )
```

setDescription

Parameters

_description

17.481 SimulatorSessionService::ModelInfoResult Struct Reference

Describes the currently active model information for a session.
`#include <applications/worker/service/SimulatorSessionService.h>`

Public Attributes

- bool **exists** = false
- unsigned int **modelId** = 0
- bool **hasChanged** = false
- unsigned int **level** = 0
- std::string **name**
- std::string **analystName**
- std::string **projectTitle**
- std::string **version**
- std::string **description**
- unsigned int **componentCount** = 0

17.481.1 Detailed Description

Describes the currently active model information for a session.
The documentation for this struct was generated from the following file:

- applications/worker/service/SimulatorSessionService.h

17.482 ModelInspectorController Class Reference

Controller for model inspection views and scene-selection synchronization.
`#include <applications/gui/genesys/controllers/ModelInspectorController.h>`

Classes

- struct DataDefinitionSelection

Public Member Functions

- **ModelInspectorController** (Simulator ∗simulator, QTreeWidget ∗componentsTree, QTreeWidget ∗data↩ DefinitionsTree, ModelGraphicsView ∗graphicsView)

  Creates the model-inspector delegated controller.
- void **actualizeModelComponents** (bool force) const

  Synchronizes the Components tree from the current model representation.
- void **actualizeModelDataDefinitions** (bool force) const

  Synchronizes the Data Definitions tree from current model data definitions.
- void **beginDataDefinitionNameEdit** (QTreeWidgetItem ∗item, int column) const

  Starts in-place rename editing for editable data-definition entries.
- void **applyDataDefinitionNameChange** (QTreeWidgetItem ∗item, int column) const

  Commits edited data-definition names back to the kernel model.

- void **syncSelectedComponentTreeItemToScene** () const

  Synchronizes tree selection with scene selection and viewport focus.
- DataDefinitionSelection **syncSelectedDataDefinitionTreeItemToScene** () const

  Synchronizes Data Definitions tree selection with visible GMDDs, when any.

17.482.1 Detailed Description

Controller for model inspection views and scene-selection synchronization.
In the refactored GUI architecture, this controller receives delegated callbacks from MainWindow to keep model-inspector responsibilities outside the composition root while preserving the existing UI contract. It synchronizes Components/Data Definitions trees with the current kernel model and keeps tree-to-scene selection behavior consistent.
Responsibilities:

- refresh model component and data-definition trees from Simulator state;
- manage in-place rename flow for editable data-definition names;
- propagate current tree selection to the graphical scene and viewport.

Boundaries:

- it does not create/destroy models or files (model lifecycle remains elsewhere);
- it does not own scene command logic, undo/redo, or simulation commands;
- it does not act as a persistence or export service.

The documentation for this class was generated from the following files:

- applications/gui/genesys/controllers/ModelInspectorController.h
- applications/gui/genesys/controllers/ModelInspectorController.cpp

17.483 ModelLanguageSynchronizer Class Reference

Service layer that synchronizes textual model language with kernel model state.
`#include <applications/gui/genesys/services/ModelLanguageSynchronizer.h>`

Public Member Functions

- ModelLanguageSynchronizer (Simulator *simulator, QPlainTextEdit *modelTextEditor, bool *textModelHas↩ ChangedFlag, QWidget *ownerWidget, std::function< void()> onModelCreatedOrLoaded)

  Creates the synchronization service used by MainWindow compatibility wrappers.
- void actualizeModelSimLanguage () const

  Rebuilds textual model representation from the current kernel model.
- bool setSimulationModelBasedOnText () const

  Parses text editor content and applies it to the simulator model.

17.483.1 Detailed Description

Service layer that synchronizes textual model language with kernel model state.
This service was extracted from MainWindow representation code to isolate text/model synchronization concerns. MainWindow remains the composition root and delegates wrapper methods to this class.
Responsibilities:

- generate/update the textual model representation from current Simulator model;
- parse/apply textual edits back into simulator model state;
- notify MainWindow via callback when model creation/loading side effects are required.

Boundaries:

- it does not own simulator or editor widgets;
- it does not handle graphical persistence, Graphviz export, or C++ code export;
- it is a synchronization service, not a controller.

17.483.2 Constructor & Destructor Documentation

17.483.2.1 ModelLanguageSynchronizer()

```
ModelLanguageSynchronizer::ModelLanguageSynchronizer (
            Simulator * simulator,
            QPlainTextEdit * modelTextEditor,
            bool * textModelHasChangedFlag,
            QWidget * ownerWidget,
            std::function< void()> onModelCreatedOrLoaded )
```

Creates the synchronization service used by MainWindow compatibility wrappers.
Stores explicit dependencies once to keep wrapper calls thin.

17.483.3 Member Function Documentation

17.483.3.1 actualizeModelSimLanguage()

```
void ModelLanguageSynchronizer::actualizeModelSimLanguage ( ) const
```

Rebuilds textual model representation from the current kernel model.
Regenerates the text editor content from the current kernel model.
This is part of the synchronization bridge used after lifecycle, property, and scene updates.

17.483.3.2 setSimulationModelBasedOnText()

```
bool ModelLanguageSynchronizer::setSimulationModelBasedOnText ( ) const
```

Parses text editor content and applies it to the simulator model.
Applies the text editor content to the current kernel model.

Returns

true when synchronization succeeds and model state is valid for downstream workflows.

The documentation for this class was generated from the following files:

- applications/gui/genesys/services/ModelLanguageSynchronizer.h
- applications/gui/genesys/services/ModelLanguageSynchronizer.cpp

17.484 ModelLifecycleController Class Reference

Controller for model/application lifecycle flows delegated from MainWindow.
`#include <applications/gui/genesys/controllers/ModelLifecycleController.h>`

Classes

- struct Callbacks

Public Member Functions

- **ModelLifecycleController** (QWidget ∗ownerWidget, Simulator ∗simulator, Ui::MainWindow ∗ui, QString ∗modelFilename, bool ∗textModelHasChanged, bool ∗graphicalModelHasChanged, bool ∗closingApproved, bool ∗loaded, bool &parallelizationEnabled, int &parallelizationThreads, int &parallelizationBatchSize, Callbacks callbacks)

  Creates the lifecycle orchestration controller used by MainWindow wrappers.

- void **onActionModelNewTriggered** () const

  Starts the new-model lifecycle flow and reinitializes GUI/model state.
- void **onActionModelOpenTriggered** () const

  Starts model-open flow with persistence loading and UI synchronization.
- bool **openModelFile** (const QString &fileName) const

  Opens a model from an explicit file path using the same lifecycle flow as the open action.
- void **onActionModelSaveTriggered** () const

  Starts model-save flow for graphical/text representations.
- void **onActionModelCloseTriggered** () const

  Closes current model after pending-change checks and cleanup orchestration.
- void **onActionModelInformationTriggered** () const

  Opens model information dialog for the current model context.
- void **onActionModelCheckTriggered** () const

  Runs model-check workflow as a delegated lifecycle operation.
- void **onActionSimulationConfigureTriggered** () const

  Opens simulation configuration workflow anchored to lifecycle façade.
- void **onActionSimulatorExitTriggered** () const

  Executes application-exit flow with pending-change confirmation semantics.
- bool **hasPendingModelChanges** () const

  Indicates whether current model/text state has unsaved changes.
- bool **confirmApplicationExit** () const

  Requests exit confirmation preserving compatibility prompt behavior.

17.484.1 Detailed Description

Controller for model/application lifecycle flows delegated from MainWindow.
This controller centralizes lifecycle actions (new/open/save/close/check/configure/exit) while MainWindow remains the composition root and compatibility façade. It uses explicit callback injection to invoke existing UI update and persistence routines without changing signatures or ownership.
Responsibilities:

- orchestrate user-triggered lifecycle actions and guard pending-change confirmations;
- coordinate model load/save paths through injected serializer callbacks;
- trigger UI/tab/action refreshes required after lifecycle transitions.

Boundaries:

- it does not directly implement file formats (delegated to services);
- it does not own simulator/model objects;
- it does not manage scene tools, property editor internals, or simulation traces.

The documentation for this class was generated from the following files:

- applications/gui/genesys/controllers/ModelLifecycleController.h
- applications/gui/genesys/controllers/ModelLifecycleController.cpp

17.485 ModelManager Class Reference

The ModelManager class.
`#include <kernel/simulator/model/ModelManager.h>`

Public Member Functions

- ModelManager (Simulator *simulator)

  Creates a model manager bound to a simulator instance.
- virtual ~**ModelManager** ()

  Releases the model manager and any owned bookkeeping structures.
- Model * newModel ()

  Creates a new model, inserts it into the open-model list and makes it current.
- void insert (Model *model)

  Inserts an existing model into the open-model list.
- void remove (Model *model)

  Removes a model from the open-model list.
- bool setCurrent (Model *model)

  Makes an open model the current one.
- bool saveModel (std::string filename)

  Saves the current model to a file.
- Model * loadModel (std::string filename)

  Loads a model from a file and opens it in the manager.
- Model * createFromLanguage (std::string modelSpecification)

  Creates a model from a textual model specification.
- unsigned int size ()

  Returns the number of open models.
- std::vector< Model * > models () const

  Returns a stable snapshot of the currently open models in tab/navigation order.
- bool hasModel (Model *model) const

  Checks whether a model is owned by this manager.
- int indexOf (Model *model) const

  Returns the open-model index of a model.
- Model * modelAt (unsigned int index) const

  Returns the model at a given open-model index.
- int currentIndex () const

  Returns the index of the current model.
- Model * front ()

  Returns the first open model.
- Model * last ()

  Returns the last open model.
- Model * current ()

  Returns the current model.
- Model * next ()

  Advances to the next open model.
- Model * previous ()

  Moves to the previous open model.
- bool canGoNext () const

  Indicates whether a next model exists.
- bool canGoPrevious () const

  Indicates whether a previous model exists.

17.485.1 Detailed Description

The ModelManager class.

17.485.2 Constructor & Destructor Documentation

17.485.2.1 ModelManager()

```
ModelManager::ModelManager (
            Simulator * simulator )
```

Creates a model manager bound to a simulator instance.

Parameters

simulator	Parent simulator that owns this manager.

17.485.3 Member Function Documentation

17.485.3.1 canGoNext()

```
bool ModelManager::canGoNext ( ) const
```

Indicates whether a next model exists.

Returns

`true` when a call to `next()` can advance.

17.485.3.2 canGoPrevious()

```
bool ModelManager::canGoPrevious ( ) const
```

Indicates whether a previous model exists.

Returns

`true` when a call to `previous()` can retreat.

17.485.3.3 createFromLanguage()

```
Model * ModelManager::createFromLanguage (
            std::string modelSpecification )
```

Creates a model from a textual model specification.

Parameters

modelSpecification	Source text in the model language.

Returns

Newly created model instance, or `nullptr` on failure.

17.485.3.4 current()

```
Model * ModelManager::current ( )
```

Returns the current model.

Returns

Currently selected model, or `nullptr` when none is selected.

17.485.3.5 currentIndex()

```
int ModelManager::currentIndex ( ) const
```

Returns the index of the current model.

Returns

Zero-based current model index, or -1 when there is no current model.

17.485.3.6 front()

```
Model * ModelManager::front ( )
```

Returns the first open model.

Returns

First model in open-model order, or `nullptr` when empty.

17.485.3.7 hasModel()

```
bool ModelManager::hasModel (
            Model * model ) const
```

Checks whether a model is owned by this manager.

Parameters

model	Model pointer to test.

Returns

True when model is in the open-model list.

17.485.3.8 indexOf()

```
int ModelManager::indexOf (
            Model * model ) const
```

Returns the open-model index of a model.

Parameters

model	Model pointer to locate.

Returns

Zero-based index, or -1 when not open.

17.485.3.9 insert()

```
void ModelManager::insert (
            Model * model )
```

Inserts an existing model into the open-model list.

Parameters

model	Model to register.

17.485.3.10 last()

```
Model * ModelManager::last ( )
```

Returns the last open model.

Returns

Last model in open-model order, or `nullptr` when empty.

17.485.3.11 loadModel()

```
Model * ModelManager::loadModel (
            std::string filename )
```

Loads a model from a file and opens it in the manager.

Parameters

filename	Input filename.

Returns

Loaded model instance, or `nullptr` on failure.

17.485.3.12 modelAt()

```
Model * ModelManager::modelAt (
            unsigned int index ) const
```

Returns the model at a given open-model index.

Parameters

index	Zero-based model index.

Returns

Model pointer, or nullptr when index is out of range.

17.485.3.13 models()

```
std::vector< Model * > ModelManager::models ( ) const
```

Returns a stable snapshot of the currently open models in tab/navigation order.

Returns

Vector with the open model pointers owned by this manager.

17.485.3.14 newModel()

```
Model * ModelManager::newModel ( )
```

Creates a new model, inserts it into the open-model list and makes it current.

Returns

The newly opened current model.

17.485.3.15 next()

```
Model * ModelManager::next ( )
```

Advances to the next open model.

Returns

Next model in order, or `nullptr` when already at the end.

17.485.3.16 previous()

```
Model * ModelManager::previous ( )
```

Moves to the previous open model.

Returns

Previous model in order, or `nullptr` when already at the beginning.

17.485.3.17 remove()

```
void ModelManager::remove (
            Model * model )
```

Removes a model from the open-model list.

Parameters

model	Model to remove.

17.485.3.18 saveModel()

```
bool ModelManager::saveModel (
            std::string filename )
```

Saves the current model to a file.

Parameters

filename	Output filename.

Returns

`true` when saving succeeds.

17.485.3.19 setCurrent()

```
bool ModelManager::setCurrent (
            Model * model )
```

Makes an open model the current one.

Parameters

model	Model to activate.

Returns

`true` when the model was found and selected.

17.485.3.20 size()

```
unsigned int ModelManager::size ( )
```

Returns the number of open models.

Returns

Open-model count.

Friends

- class **Model**

17.488.1 Detailed Description

Controls the mature, currently functional simulation-execution layer of a model.
The ModelSimulation controls the simulation of a model, alowing to start, pause, resume e stop a simulation, composed by a set of replications.
Historically, this class has been the original and operational experiment mechanism in GenESyS. It already supports the core execution workflow based on replications, replication length, warm-up configuration and event processing. Later experiment-oriented classes such as SimulationExperiment and SimulationScenario were introduced as an attempt to move richer design-of-experiments concerns into the kernel. Those newer classes are still under development, while ModelSimulation remains the stable execution core.

17.488.2 Member Function Documentation

17.488.2.1 isRunning()

```
bool ModelSimulation::isRunning ( ) const
```

The current time in the model being simulated, i.e., the instant when the current event was triggered

17.488.2.2 start()

```
void ModelSimulation::start ( )
```

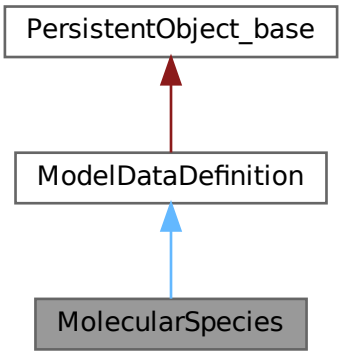
Starts a sequential execution of a simulation, ie, a set of replications of this model.
Checks the model and if ok then initialize the simulation, execute repeatedly each replication and then show simulation statistics
The documentation for this class was generated from the following files:

- kernel/simulator/model/ModelSimulation.h
- kernel/simulator/model/ModelSimulation.cpp

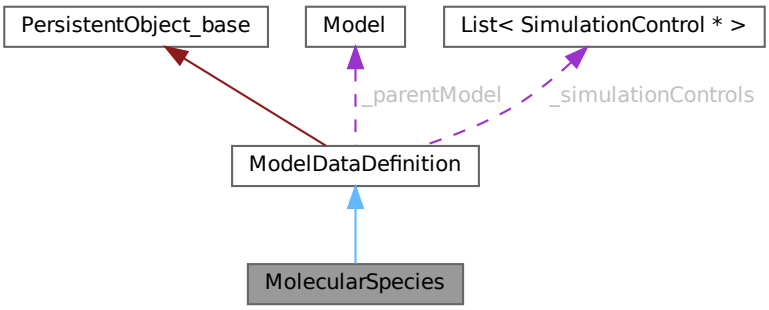
17.489 MolecularSpecies Class Reference

```
#include <plugins/data/WholeCellModeling/MolecularSpecies.h>
```

Inheritance diagram for MolecularSpecies:



Collaboration diagram for MolecularSpecies:



Public Member Functions

- **MolecularSpecies** (Model *model, std::string name="")
- void **setInitialCount** (int initialCount)
- int **getInitialCount** () const
- void **setCount** (int count)
- int **getCount** () const
- void **setCompartment** (std::string compartment)
- std::string **getCompartment** () const
- void **setUnit** (std::string unit)
- std::string **getUnit** () const
- virtual std::string show () override

  Returns a textual representation of this data definition.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

Creates a model data definition and optionally inserts it into the model.

- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.

- Util::identification getId () const

  Returns the unique identifier of this instance.

- void setName (const std::string &name)

  Updates the logical name of this instance.

- const std::string & getName () const

  Returns the logical name of this instance.

- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.

- const std::string & getLabel () const

  Returns the user-visible label of this instance.

- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.

- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.

- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.

- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.

- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.

- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.

- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.

- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.

- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.

- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.

- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.

- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.

- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

17.489.1 Detailed Description

Discrete molecular species with integer copy count for Gillespie SSA.
Unlike BioSpecies (continuous double amounts for ODE), MolecularSpecies tracks integer molecule counts. Compartment and unit annotate the biological context without affecting simulation logic.

17.489.2 Member Function Documentation

17.489.2.1 _check()

```
bool MolecularSpecies::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.489.2.2 _initBetweenReplications()

```
void MolecularSpecies::_initBetweenReplications ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.489.2.3 _loadInstance()

```
bool MolecularSpecies::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.489.2.4 _saveInstance()

```
void MolecularSpecies::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.

17.489.2.5 show()

```
std::string MolecularSpecies::show ( )  [override], [virtual]
```

Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from ModelDataDefinition.

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes
- virtual void _createInternalStatisticReporters () override
- virtual void _createEditableDataDefinitions () override
- virtual void _createAttachedAttributes () override

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual ParserChangesInformation * _getParserChangesInformation ()
- virtual void _initBetweenReplications ()
- virtual void _addSimulationControl (SimulationControl *control)
- virtual void _createInternalAndAttachedData ()

17.491.1 Detailed Description

Minimal transporter movement component.
This component intentionally collapses Arena's request/transport/free chain into one atomic operation suitable for the current closeout: reserve one transporter, move the entity to a destination station using the attached Distance set, and free the transporter on arrival.

17.491.2 Member Function Documentation

17.491.2.1 _check()

```
bool Move::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.491.2.2 _createAttachedAttributes()

```
void Move::_createAttachedAttributes ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.491.2.3 _createEditableDataDefinitions()

```
void Move::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.491.2.4 _createInternalStatisticReporters()

```
void Move::_createInternalStatisticReporters ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.491.2.5 _loadInstance()

```
bool Move::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.491.2.6 _onDispatchEvent()

```
void Move::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.491.2.7 _saveInstance()

```
void Move::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.491.2.8 show()

```
std::string Move::show ( )  [override], [virtual]
```

virtual public methods

Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.

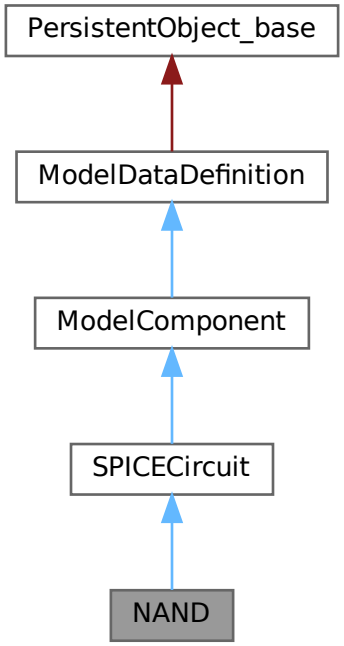
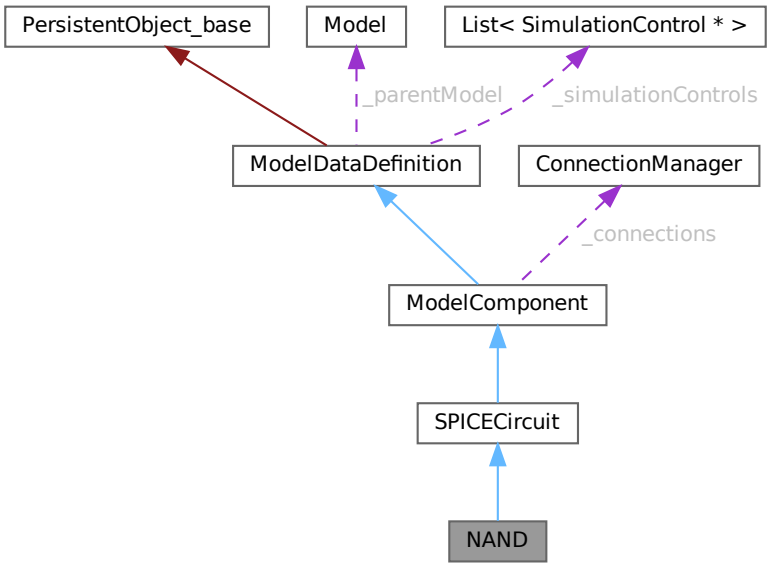
17.498 NAND Class Reference

Inheritance diagram for NAND:



Collaboration diagram for NAND:



Public Member Functions

- **NAND** (Model *model, std::string name="")
- void Build () override
- void **setPMOSWidth** (float PMOSWidth)
- void **setPMOSLength** (float length)
- void **setNMOSWidth** (float NMOSWidth)
- void **setNMOSLength** (float NMOSLength)
- void **setElectricalModel** (std::string electricalModel)

Public Member Functions inherited from SPICECircuit

- **SPICECircuit** (Model *model, std::string name="")

  constructors
- void **setRunner** (SPICERunner *runner)

  new public user methods for this components
- SPICERunner * **getRunner** ()
- virtual std::string show () override

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

Updates the user-visible label of this instance.

- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from SPICECircuit

- static PluginInformation * **GetPluginInformation** ()

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")
- static std::vector< std::string > **split** (std::string word, char split_char)

  Externalize function GetPluginInformation to be accessible throught dynamic linked library.

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.

Protected Member Functions inherited from SPICECircuit

17.498.1 Member Function Documentation

17.498.1.1 _loadInstance()

```
bool NAND::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from SPICECircuit.

17.498.1.2 _saveInstance()

```
void NAND::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from SPICECircuit.

17.498.1.3 Build()

```
void NAND::Build ( )  [override], [virtual]
```

Reimplemented from SPICECircuit.
The documentation for this class was generated from the following files:

- plugins/components/ModalModel/CellularAutomata/Neighborhood_VonNeumann.h

17.505 NetworkActivationFrame Class Reference

Input side of one `DefaultNetwork::activate()` call: the presence and value of every declared input port for this activation only.
`#include <plugins/data/ModalModel/NetworkActivation.h>`

Public Member Functions

- **NetworkActivationFrame** (unsigned int numInputs=0)
- void **reset** (unsigned int numInputs)

  Resizes the frame, clearing every input to absent.
- unsigned int **size** () const
- void **setPresent** (unsigned int index, double value)

  Marks input `index` present with `value`. No-op when `index` is out of range.
- void **setAbsent** (unsigned int index)

  Marks input `index` absent (value reads back as 0.0). No-op when `index` is out of range.
- bool **isPresent** (unsigned int index) const
- double **getValue** (unsigned int index) const

  Returns the input value, or 0.0 when absent or out of range.

17.505.1 Detailed Description

Input side of one `DefaultNetwork::activate()` call: the presence and value of every declared input port for this activation only.
A frame is a short-lived, per-activation value object. It is not persistent network state (see `DefaultNetwork::getLastInputValue()` for the separate, optional last-observed-value concept described in architecture reference §13).
The ordinary GenESyS `ModalModel` adapter normally marks only the input port that received the arriving entity as present (architecture reference §12); this class itself places no such restriction, so a future multi-input activation remains representable.
The documentation for this class was generated from the following files:

- plugins/data/ModalModel/NetworkActivation.h
- plugins/data/ModalModel/NetworkActivation.cpp

17.506 NetworkActivationResult Class Reference

Output side of one `DefaultNetwork::activate()` call: the presence and value of every declared output port produced by that activation.
`#include <plugins/data/ModalModel/NetworkActivation.h>`

Public Member Functions

- **NetworkActivationResult** (unsigned int numOutputs=0)
- void **reset** (unsigned int numOutputs)

  Resizes the result, clearing every output to absent.
- unsigned int **size** () const
- void **setPresent** (unsigned int index, double value)
- void **setAbsent** (unsigned int index)
- bool **isPresent** (unsigned int index) const
- double **getValue** (unsigned int index) const
- unsigned int **countPresent** () const

  Returns how many output ports are currently present.

17.506.1 Detailed Description

Output side of one `DefaultNetwork::activate()` call: the presence and value of every declared output port produced by that activation.
See architecture reference §15/§17: only present outputs cause the `ModalModel` adapter to route/consume/clone the process entity. An absent output is not interpreted as zero.
The documentation for this class was generated from the following files:

- plugins/data/ModalModel/NetworkActivation.h
- plugins/data/ModalModel/NetworkActivation.cpp

17.507 NetworkPortValue Struct Reference

Presence/value pair carried by one network port during one activation.
`#include <plugins/data/ModalModel/NetworkActivation.h>`

Public Attributes

- bool **present** = false
- double **value** = 0.0

17.507.1 Detailed Description

Presence/value pair carried by one network port during one activation.
See `docs/ai_assistants/reference/GENESYS_MODAL_MODEL_NETWORK_ARCHITECTURE.md` §8/§12: an absent port is not equivalent to a present port whose value is zero, and is not equivalent to reusing a previous value. `value` is only meaningful when `present` is `true`.
The value is numeric (`double`) in this first implementation, matching the current GenESyS parser/expression contract (§20 of the architecture reference); this does not prevent a future typed/vector/matrix port value, which would extend this struct rather than replace its presence semantics.
The documentation for this struct was generated from the following file:

- plugins/data/ModalModel/NetworkActivation.h

17.508 genesys::launcher::NetworkRequestOptions Struct Reference

Public Attributes

- qint64 **maximumBytes** = 1024 ∗ 1024
- int **timeoutMs** = 8000
- int **maximumRedirects** = 3
- bool **httpsOnly** = true

The documentation for this struct was generated from the following file:

- applications/launcher/NetworkTransport.h

17.509 genesys::launcher::NetworkResponse Struct Reference

Public Attributes

- bool **ok** = false
- bool **cancelled** = false
- int **httpStatus** = 0
- qint64 **bytesReceived** = 0
- QUrl **finalUrl**
- QString **error**

The documentation for this struct was generated from the following file:

- applications/launcher/NetworkTransport.h

17.510 ParserManager::NewParser Struct Reference

Paths associated with a generated parser artifact set.
`#include <kernel/simulator/ParserManager.h>`

Public Attributes

- std::string **bisonFilename**
- std::string **flexFilename**
- std::string **compiledParserFilename**

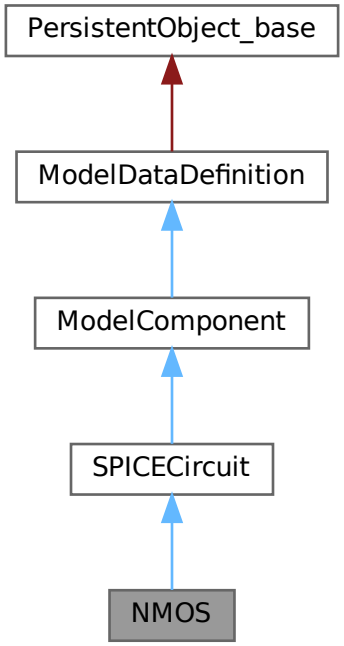
17.510.1 Detailed Description

Paths associated with a generated parser artifact set.
The documentation for this struct was generated from the following file:

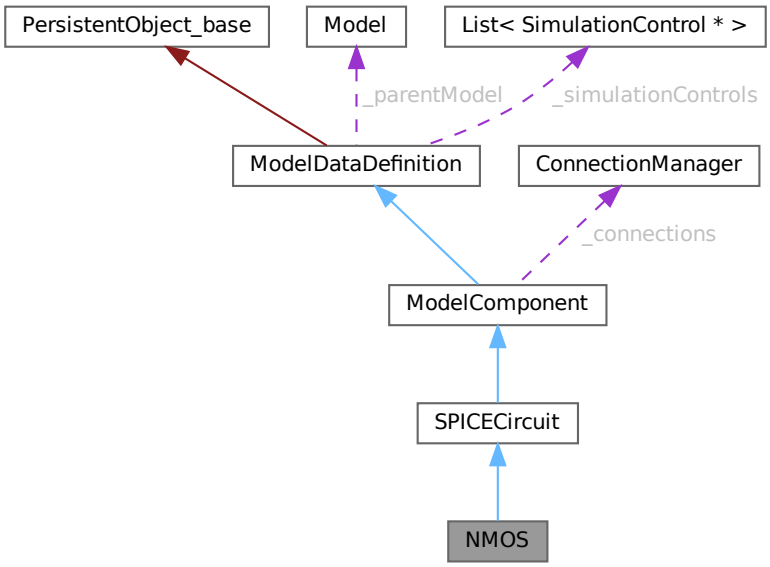
- kernel/simulator/ParserManager.h

17.511 NMOS Class Reference

Inheritance diagram for NMOS:



Collaboration diagram for NMOS:



Public Member Functions

- **NMOS** (Model *model, std::string name="")
- void Build () override
- void **setWidth** (float width)
- void **setLength** (float length)
- void **setElectricalModel** (std::string electricalModel)

Public Member Functions inherited from SPICECircuit

- **SPICECircuit** (Model *model, std::string name="")

  constructors
- void **setRunner** (SPICERunner *runner)

  new public user methods for this components
- SPICERunner * **getRunner** ()
- virtual std::string show () override

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

Returns the user-visible label of this instance.

- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.

- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.

- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.

- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.

- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.

- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.

- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.

- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.

- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.

- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.

- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.

- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.

- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from SPICECircuit

- static PluginInformation * **GetPluginInformation** ()

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component

- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")
- static std::vector< std::string > **split** (std::string word, char split_char)

  Externalize function GetPluginInformation to be accessible throught dynamic linked library.

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.

Protected Member Functions inherited from SPICECircuit

- void **BuildCircuit** (std::string description, unsigned int id, std::vector< std::string > the_params={""}, std::string the_model="", std::string the_model_file="")

  virtual protected method that must be overriden

17.511.1 Member Function Documentation

17.511.1.1 _loadInstance()

```
bool NMOS::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from SPICECircuit.

17.511.1.2 _saveInstance()

```
void NMOS::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from SPICECircuit.

17.511.1.3 Build()

```
void NMOS::Build ( )  [override], [virtual]
```

Reimplemented from SPICECircuit.
The documentation for this class was generated from the following files:

- plugins/components/ElectronicsSimulation/SPICECircuit.h
- plugins/components/ElectronicsSimulation/SPICECircuit.cpp

17.512 testing::internal::None Struct Reference

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

Connects this component to another component.

- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.

- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.

- std::string getDescription () const

  Returns the free-form description associated with this component.

- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.

- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.

- Util::identification getId () const

  Returns the unique identifier of this instance.

- void setName (const std::string &name)

  Updates the logical name of this instance.

- const std::string & getName () const

  Returns the logical name of this instance.

- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.

- const std::string & getLabel () const

  Returns the user-visible label of this instance.

- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.

- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.

- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.

- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.

- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.

- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.

- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.

- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.

- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

- void **_mandatoryAttachedAttributeInsert** (const std::string &key, ModelDataDefinition *data)
- void **_mandatoryAttachedAttributeRemove** (const std::string &key)

- void **_mandatoryAttachedAttributesClear** ()
- void **_mandatoryEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_mandatoryEditableDataDefinitionRemove** (const std::string &key)
- void **_mandatoryEditableDataDefinitionsClear** ()
- void **_optionalEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_optionalEditableDataDefinitionRemove** (const std::string &key)
- void **_optionalEditableDataDefinitionsClear** ()
- void **_mandatoryNonEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_mandatoryNonEditableDataDefinitionRemove** (const std::string &key)
- void **_mandatoryNonEditableDataDefinitionsClear** ()
- void **_optionalNonEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_optionalNonEditableDataDefinitionRemove** (const std::string &key)
- void **_optionalNonEditableDataDefinitionsClear** ()
- void **_checkCreateAttachedReferencedDataDefinition** (const std::string &expression)

  method to be called to insert attached dataelements that are referenced by string expressions (detected by the parser), to avoid orphaned data definitions
- void **trace** (const std::string &text, TraceManager::Level level=TraceManager::Level::L8_detailed)

  not just an easy access to trace manager, but wrappers to check if specific trace level applies
- void **traceError** (const std::string &text, const std::exception &e)
- void **traceError** (const std::string &text, TraceManager::Level level=TraceManager::Level::L1_errorFatal)
- void **traceReport** (const std::string &text, TraceManager::Level level=TraceManager::Level::L2_results)
- void **traceSimulation** (void *thisobject, double time, Entity *entity, ModelComponent *component, const std::string &text, TraceManager::Level level=TraceManager::Level::L8_detailed)
- void traceSimulation (void *thisobject, const std::string &text, TraceManager::Level level=TraceManager::↩ Level::L8_detailed)

  Traces text to the simulation output.
- void **traceSimulation** (void *thisobject, TraceManager::Level level, const std::string &text)

17.513.1 Member Function Documentation

17.513.1.1 _loadInstance()

```
bool NOR::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from SPICECircuit.

17.513.1.2 _saveInstance()

```
void NOR::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from SPICECircuit.

17.513.1.3 Build()

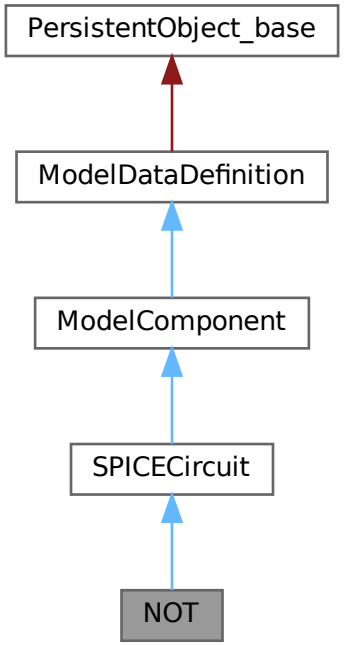
```
void NOR::Build ( )  [override], [virtual]
```

Reimplemented from SPICECircuit.
The documentation for this class was generated from the following files:

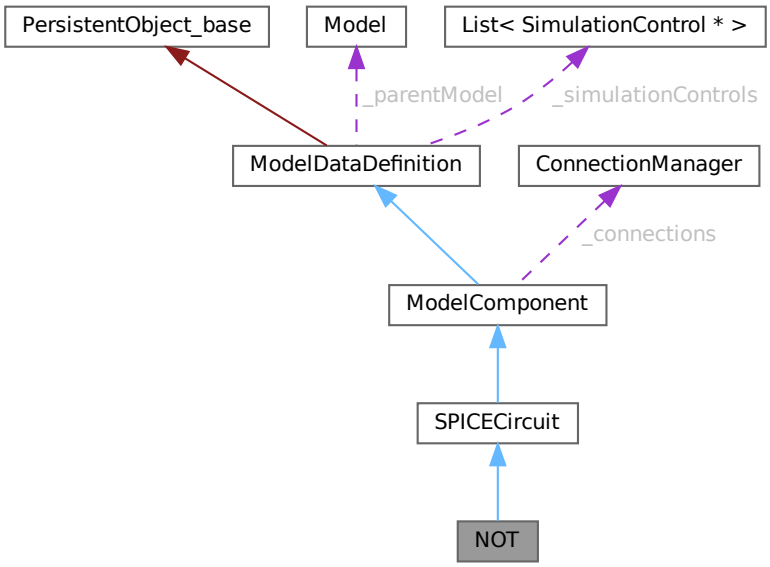
- plugins/components/ElectronicsSimulation/SPICECircuit.h
- plugins/components/ElectronicsSimulation/SPICECircuit.cpp

17.514 NOT Class Reference

Inheritance diagram for NOT:



Collaboration diagram for NOT:



Public Member Functions

- **NOT** (Model *model, std::string name="")
- void Build () override
- void **setPMOSWidth** (float PMOSWidth)
- void **setPMOSLength** (float length)
- void **setNMOSWidth** (float NMOSWidth)
- void **setNMOSLength** (float NMOSLength)
- void **setElectricalModel** (std::string electricalModel)

Public Member Functions inherited from SPICECircuit

- **SPICECircuit** (Model *model, std::string name="")

  constructors
- void **setRunner** (SPICERunner *runner)

  new public user methods for this components
- SPICERunner * **getRunner** ()
- virtual std::string show () override

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

Updates the user-visible label of this instance.

- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from SPICECircuit

- static PluginInformation * **GetPluginInformation** ()

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")
- static std::vector< std::string > **split** (std::string word, char split_char)

  Externalize function GetPluginInformation to be accessible throught dynamic linked library.

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.

Protected Member Functions inherited from SPICECircuit

- void **BuildCircuit** (std::string description, unsigned int id, std::vector< std::string > the_params={""}, std::string the_model="", std::string the_model_file="")

  virtual protected method that must be overriden
- void **UpdateConnections** ()
- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  This method is only for ModelComponents, not ModelDataElements.
- virtual void _createNonEditableDataDefinitions () override

  virtual protected methods that could be overriden by derived classes, if needed

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual bool _check (std::string &errorMessage)

  could be overriden by derived classes
- virtual ParserChangesInformation * _getParserChangesInformation ()

17.514.1 Member Function Documentation

17.514.1.1 _loadInstance()

```
bool NOT::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from SPICECircuit.

17.514.1.2 _saveInstance()

```
void NOT::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from SPICECircuit.

17.514.1.3 Build()

```
void NOT::Build ( )  [override], [virtual]
```

Reimplemented from SPICECircuit.
The documentation for this class was generated from the following files:

- plugins/components/ElectronicsSimulation/SPICECircuit.h
- plugins/components/ElectronicsSimulation/SPICECircuit.cpp

17.515 obj_t Class Reference

Public Member Functions

- **obj_t** (double v, std::string t)
- **obj_t** (double v, std::string t, unsigned long uid)

Public Attributes

- double **valor**
- std::string **tipo**

17.516 Optimizer_if::ObjectiveDefinition Struct Reference

Configurable objective definition.
`#include <tools/Optimization/Optimizer_if.h>`

Public Attributes

- std::string **name**
- ObjectiveSense **sense**
- std::string **expression**
- double **weight** = 1.0
- bool **enabled** = true

17.516.1 Detailed Description

Configurable objective definition.
The expression is parsed by the model/parser context and can reference selected responses, controls, constants or user-defined expressions.
The documentation for this struct was generated from the following file:

- tools/Optimization/Optimizer_if.h

- void collapsed (QtBrowserItem *item)
- void expanded (QtBrowserItem *item)

Signals inherited from QtAbstractPropertyBrowser

- void currentItemChanged (QtBrowserItem *)

Properties inherited from QtTreePropertyBrowser

- int **indentation**

  indentation of the items in the tree view.
- bool **rootIsDecorated**

  whether to show controls for expanding and collapsing root items.
- bool **alternatingRowColors**

  whether to draw the background using alternating colors. By default this property is set to true.
- bool **headerVisible**

  whether to show the header.
- ResizeMode **resizeMode**

  the resize mode of setions in the header.
- int **splitterPosition**

the position of the splitter between the columns.

- bool propertiesWithoutValueMarked

  whether to enable or disable marking properties without value.

The documentation for this class was generated from the following files:

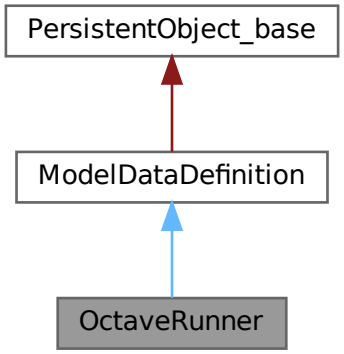
- applications/gui/genesys/propertyeditor/ObjectPropertyBrowser.h
- applications/gui/genesys/propertyeditor/ObjectPropertyBrowser.cpp

17.518 OctaveRunner Class Reference

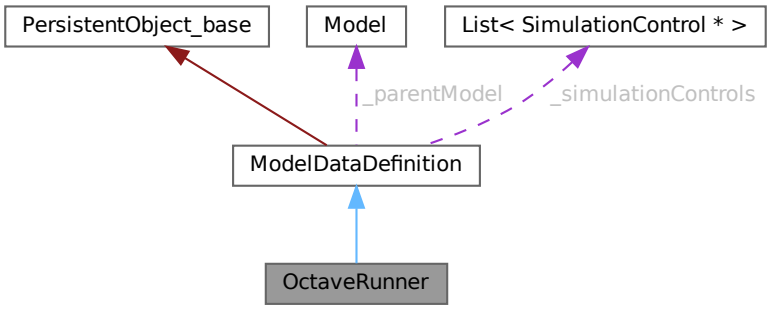
Model data definition that executes Octave code through Rscript.

`#include <plugins/data/ExternalIntegration/OctaveRunner.h>`

Inheritance diagram for OctaveRunner:



Collaboration diagram for OctaveRunner:



Public Member Functions

- **OctaveRunner** (Model *model, std::string name="")

  Creates an Octave Runner bound to a model.

- virtual ~**OctaveRunner** ()=default

Destroys the Octave Runner.

- void **setOctaveExecutable** (std::string octaveExecutable)

  Sets the Rscript executable name or path.
- std::string **getOctaveExecutable** () const

  Returns the Rscript executable name or path.
- void **setWorkingDirectory** (std::string workingDirectory)

  Sets the working directory used for generated scripts and command execution.
- std::string **getWorkingDirectory** () const

  Returns the working directory used for generated scripts and command execution.
- void **setPreludeScript** (std::string preludeScript)

  Sets optional Octave code prepended before the command block.
- std::string **getPreludeScript** () const

  Returns optional Octave code prepended before the command block.
- void **setCommand** (std::string command)

  Sets the Octave command/script body to execute.
- std::string **getCommand** () const

  Returns the Octave command/script body to execute.
- void **setLastStatus** (std::string lastStatus)

  Sets the last execution status.
- std::string **getLastStatus** () const

  Returns the last execution status.
- void **setLastExitCode** (int lastExitCode)

  Sets the last process exit code.
- int **getLastExitCode** () const

  Returns the last process exit code.
- void **setLastStdout** (std::string lastStdout)

  Sets stdout captured from the last Octave execution.
- std::string **getLastStdout** () const

  Returns stdout captured from the last Octave execution.
- void **setLastStderr** (std::string lastStderr)

  Sets stderr captured from the last Octave execution.
- std::string **getLastStderr** () const

  Returns stderr captured from the last Octave execution.
- void **setLastResponsePayload** (std::string lastResponsePayload)

  Sets the response payload exposed to other tools.
- std::string **getLastResponsePayload** () const

  Returns the response payload exposed to other tools.
- void **setLastScriptFilename** (std::string lastScriptFilename)

  Sets the generated Octave script filename from the last execution.
- std::string **getLastScriptFilename** () const

  Returns the generated Octave script filename from the last execution.
- void **setLastResponseFilename** (std::string lastResponseFilename)

  Sets the stdout file path from the last execution.
- std::string **getLastResponseFilename** () const

  Returns the stdout file path from the last execution.
- bool **executeCommand** (std::string &errorMessage)

  Executes the configured Octave code and updates last-execution fields atomically.
- virtual std::string show () override

  Returns a compact human-readable description of the runner.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insertIntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecificEnabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static ModelDataDefinition * **LoadInstance** (Model *model, PersistenceRecord *fields)

  Loads an Octave Runner from a persistence record.
- static PluginInformation * **GetPluginInformation** ()

  Returns plugin metadata and system dependency declarations.
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

  Creates a new Octave Runner instance for plugin construction.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  Loads persisted Octave Runner configuration and last-execution state.
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves Octave Runner configuration and last-execution state.
- virtual bool _check (std::string &errorMessage) override

  Validates the runner configuration without executing Octave.

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual ParserChangesInformation * _getParserChangesInformation ()

17.518.1 Detailed Description

Model data definition that executes Octave code through Rscript.
The runner stores a compact Octave execution configuration, writes a temporary script, executes it with Rscript, and keeps status, exit code, stdout, stderr and response payload inside the model data definition for later inspection.

17.518.2 Member Function Documentation

17.518.2.1 _check()

```
bool OctaveRunner::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

Validates the runner configuration without executing Octave.
Reimplemented from ModelDataDefinition.

17.518.2.2 _loadInstance()

```
bool OctaveRunner::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

Loads persisted Octave Runner configuration and last-execution state.
Reimplemented from ModelDataDefinition.

17.518.2.3 _saveInstance()

```
void OctaveRunner::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves Octave Runner configuration and last-execution state.
Reimplemented from ModelDataDefinition.

17.518.2.4 show()

```
std::string OctaveRunner::show ( )  [override], [virtual]
```

Returns a compact human-readable description of the runner.
Reimplemented from ModelDataDefinition.
The documentation for this class was generated from the following files:

- plugins/data/ExternalIntegration/OctaveRunner.h
- plugins/data/ExternalIntegration/OctaveRunner.cpp

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

17.520.1 Member Function Documentation

17.520.1.1 _check()

```
bool ODESolver::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.520.1.2 _createEditableDataDefinitions()

```
void ODESolver::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.520.1.3 _initBetweenReplications()

```
void ODESolver::_initBetweenReplications ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.520.1.4 _loadInstance()

```
bool ODESolver::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.520.1.5 _saveInstance()

```
void ODESolver::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.

17.520.1.6 show()

```
std::string ODESolver::show ( )  [override], [virtual]
```

Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from ModelDataDefinition.
The documentation for this class was generated from the following files:

17.524.1 Member Function Documentation

17.524.1.1 _check()

```
bool OLD_ODEelement::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.524.1.2 _loadInstance()

```
bool OLD_ODEelement::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.524.1.3 _saveInstance()

```
void OLD_ODEelement::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.

17.524.1.4 show()

```
std::string OLD_ODEelement::show ( )  [override], [virtual]
```

Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from ModelDataDefinition.

17.525.1 Detailed Description

OnEventManager allows external methods to hook interval simulation events as listeners (or observers) of pecific events. All methods added as listeners of an event will be invovked when that event is triggered.
The documentation for this class was generated from the following files:

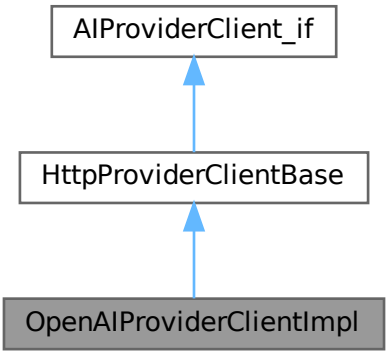
- kernel/simulator/OnEventManager.h
- kernel/simulator/OnEventManager.cpp

17.526 OpenAIProviderClientImpl Class Reference

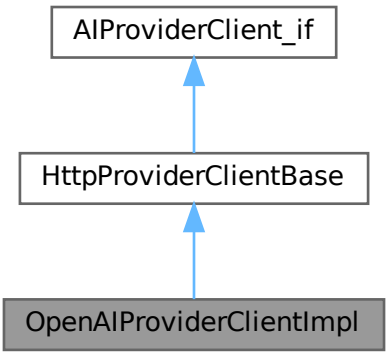
AI provider client for the OpenAI Chat Completions API.

`#include <tools/AIAssistant/OpenAIProviderClientImpl.h>`

Inheritance diagram for OpenAIProviderClientImpl:



Collaboration diagram for OpenAIProviderClientImpl:



Public Member Functions

- OpenAIProviderClientImpl ()

  Constructs the client with the standard OpenAI base URL.
- std::string getProviderName () const override

  Returns a human-readable provider name (e.g. "OpenAI", "Anthropic").
- bool isAvailable () const override

  Returns `true` when an API key is set and a base URL is configured.
- void **setOrganizationId** (const std::string &orgId)

  Sets the OpenAI organization identifier (sent as OpenAI-Organization header).

- std::string **getOrganizationId** () const

  Returns the configured organization identifier.
- void **setProjectId** (const std::string &projectId)

  Sets the OpenAI project identifier (sent as OpenAI-Project header).
- std::string **getProjectId** () const

  Returns the configured project identifier.

Public Member Functions inherited from HttpProviderClientBase

- **HttpProviderClientBase** (const HttpProviderClientBase &)=delete
- HttpProviderClientBase & **operator=** (const HttpProviderClientBase &)=delete
- void setBaseUrl (const std::string &url) override

  Sets the base URL for the provider API endpoint.
- std::string getBaseUrl () const override

  Returns the currently configured base URL.
- void setTimeoutSeconds (unsigned int seconds) override

  Sets the HTTP request timeout in seconds.
- unsigned int getTimeoutSeconds () const override

  Returns the configured HTTP request timeout.
- void setApiKey (const std::string &apiKey) override

  Stores the API key in memory.
- void clearApiKey () override

  Overwrites (best-effort) and clears the in-memory API key.
- bool hasApiKey () const override

  Returns `true` when a non-empty API key is held.
- ProviderResponse send (const ProviderRequest &request) override

  Executes the HTTP request via curl and returns the provider response.

Protected Member Functions

- std::string _buildRequestBody (const ProviderRequest &request) const override

  Serialises `request` to the provider's JSON wire format.
- ProviderResponse _parseResponseBody (const std::string &rawBody, int httpStatus) const override

  Deserialises `rawBody` (the full curl stdout) into a ProviderResponse.
- std::string _authorizationHeader () const override

  Returns the Authorization header line without the "header = " prefix.
- std::vector< std::string > _extraRequestHeaders () const override

  Returns additional HTTP headers to send with every request.

Additional Inherited Members

Static Public Member Functions inherited from HttpProviderClientBase

- static std::string **_escapeJsonString** (const std::string &s)

  Escapes a plain string for safe embedding inside a JSON string value.
- static std::string **_extractJsonString** (const std::string &json, const std::string &key)

  Extracts the value of a top-level JSON string field by key. Returns an empty string when not found or value is not a quoted string.
- static int **_extractJsonInt** (const std::string &json, const std::string &key)

  Extracts the value of a top-level JSON integer field by key. Returns 0 when not found.
- static double **_extractJsonDouble** (const std::string &json, const std::string &key)

  Extracts the value of a top-level JSON number field (int or float) by key. Returns 0.0 when not found.
- static std::string **_buildMessagesArray** (const std::vector< ChatMessage > &messages)

Serialises a vector of ChatMessage objects to a JSON array string.

- static std::string **_extractFirstArrayElement** (const std::string &json, const std::string &arrayKey)

  Extracts the raw substring of the first element of a named JSON array. Returns an empty string when not found.

Protected Attributes inherited from HttpProviderClientBase

- std::string **_baseUrl**
- unsigned int **_timeoutSeconds** = 30
- std::string _apiKey

  In-memory API key.

17.526.1 Detailed Description

AI provider client for the OpenAI Chat Completions API.
Wraps the OpenAI `/v1/chat/completions` endpoint. Default base URL: `https://api.openai.com/v1/chat/completions`
Supported features:

- Standard chat completions (gpt-4o, gpt-4-turbo, gpt-3.5-turbo, etc.).
- Reasoning models via highReasoningMode (o3, o4-mini): temperature is omitted and reasoning_effort is set to "high" in the request body.
- Organization and project headers when set via setOrganizationId() / setProjectId().

17.526.1.1 API key

Passed as `Authorization: Bearer <key>`. Stored in the parent's _apiKey member; never written to the command line or logs.

17.526.2 Constructor & Destructor Documentation

17.526.2.1 OpenAIProviderClientImpl()

```
OpenAIProviderClientImpl::OpenAIProviderClientImpl ( )
```

Constructs the client with the standard OpenAI base URL.
To use with Azure OpenAI or a compatible proxy, call setBaseUrl() after construction.

17.526.3 Member Function Documentation

17.526.3.1 _authorizationHeader()

```
std::string OpenAIProviderClientImpl::_authorizationHeader ( ) const  [override], [protected],
[virtual]
```

Returns the Authorization header line without the "header = " prefix.
Example return values:

- "Authorization: Bearer sk-..." (OpenAI, LocalProvider)
- "x-api-key: sk-ant-..." (Anthropic)

Called only from within send(); the value is written to a 0600 temp file and never logged.
Implements HttpProviderClientBase.

17.526.3.2 _buildRequestBody()

```
std::string OpenAIProviderClientImpl::_buildRequestBody (
            const ProviderRequest & request ) const  [override], [protected], [virtual]
```

Serialises `request` to the provider's JSON wire format.
Implements HttpProviderClientBase.

17.526.3.3 _extraRequestHeaders()

```
std::vector< std::string > OpenAIProviderClientImpl::_extraRequestHeaders ( ) const  [override], [protected], [virtual]
```

Returns additional HTTP headers to send with every request.
Default implementation returns an empty vector. Anthropic overrides to add "anthropic-version: 2023-06-01".
Each element must be a complete header line, e.g. "anthropic-version: 2023-06-01".
Reimplemented from HttpProviderClientBase.

17.526.3.4 _parseResponseBody()

```
ProviderResponse OpenAIProviderClientImpl::_parseResponseBody (
            const std::string & rawBody,
            int httpStatus ) const  [override], [protected], [virtual]
```

Deserialises `rawBody` (the full curl stdout) into a ProviderResponse.

Parameters

rawBody	Complete HTTP response body as received from curl.
httpStatus	HTTP status code captured from curl exit / response line, or 0 when unavailable.

Implements HttpProviderClientBase.

17.526.3.5 getProviderName()

```
std::string OpenAIProviderClientImpl::getProviderName ( ) const  [override], [virtual]
```

Returns a human-readable provider name (e.g. "OpenAI", "Anthropic").
Implements AIProviderClient_if.

17.526.3.6 isAvailable()

```
bool OpenAIProviderClientImpl::isAvailable ( ) const  [override], [virtual]
```

Returns `true` when an API key is set and a base URL is configured.
Reimplemented from HttpProviderClientBase.
The documentation for this class was generated from the following files:

- tools/AIAssistant/OpenAIProviderClientImpl.h
- tools/AIAssistant/OpenAIProviderClientImpl.cpp

17.529 Optimizer_if::OptimizationSettings Struct Reference

Generic optimization settings independent of a specific algorithm.
`#include <tools/Optimization/Optimizer_if.h>`

Public Attributes

- unsigned int **maxIterations** = 100
- unsigned int **maxSimulations** = 0
- unsigned int **replicationsPerSolution** = 1
- unsigned int **bestSolutionsToKeep** = 10
- unsigned int **randomSeed** = 0
- double **improvementTolerance** = 0.0
- double **timeLimitSeconds** = 0.0

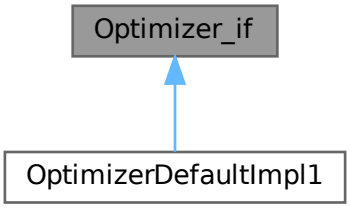
17.529.1 Detailed Description

Generic optimization settings independent of a specific algorithm.
The documentation for this struct was generated from the following file:

- tools/Optimization/Optimizer_if.h

17.530 Optimizer_if Class Reference

Interface for simulation-based optimization engines (OptQuest-like).
`#include <tools/Optimization/Optimizer_if.h>`
Inheritance diagram for Optimizer_if:



Classes

- struct ConstraintDefinition

  Feasibility restriction represented as an expression.
- struct ObjectiveDefinition

  Configurable objective definition.
- struct OptimizationSettings

  Generic optimization settings independent of a specific algorithm.
- struct SolutionSummary

  Captures one candidate or best-known optimization solution.

Public Types

- enum class ObjectiveSense { **MINIMIZE** , **MAXIMIZE** }

  Direction used by an optimization objective.
- enum class ExecutionState {
  NOT_READY , **READY** , **RUNNING** , **PAUSED** ,
  STOPPED , **FINISHED** , **ERROR** }

  Execution state of the optimization process.

Public Member Functions

- virtual void setModel (Model *model)=0

  Associates an already instantiated model with this optimizer.
- virtual bool setModelFilename (const std::string &filename)=0

  Loads/associates a model from a file supported by the simulator.
- virtual Model * getModel () const =0

  Returns the model currently associated with the optimizer.
- virtual std::string getModelFilename () const =0

  Returns the source filename previously configured for model loading.
- virtual List< SimulationControl * > * getAvailableControls () const =0

  Retrieves available model controls discoverable from Model.
- virtual List< SimulationResponse * > * getAvailableResponses () const =0

  Retrieves available model responses discoverable from Model.
- virtual void setSelectedControls (List< SimulationControl * > *controls)=0

  Replaces the set of controls selected for optimization.
- virtual void setSelectedResponses (List< SimulationResponse * > *responses)=0

  Replaces the set of responses selected for optimization.
- virtual List< SimulationControl * > * getSelectedControls () const =0

  Returns currently selected controls used as decision variables.
- virtual List< SimulationResponse * > * getSelectedResponses () const =0

  Returns currently selected responses monitored by optimization.
- virtual void addObjective (const ObjectiveDefinition &objective)=0

  Adds one objective to the optimization model.
- virtual void clearObjectives ()=0

  Clears all configured objectives.
- virtual List< ObjectiveDefinition > * getObjectives () const =0

  Returns all configured optimization objectives.
- virtual void addConstraint (const ConstraintDefinition &constraint)=0

  Adds one feasibility constraint expression.
- virtual void clearConstraints ()=0

  Clears all configured constraints.
- virtual List< ConstraintDefinition > * getConstraints () const =0

Returns all configured feasibility constraints.

- virtual void setSettings (const OptimizationSettings &settings)=0

  Applies algorithm settings such as iteration and retention limits.
- virtual OptimizationSettings getSettings () const =0

  Returns currently active optimization settings.
- virtual bool checkReady (std::string *message=nullptr) const =0

  Validates readiness before running optimization.
- virtual bool start ()=0

  Starts a new optimization run.
- virtual bool step ()=0

  Executes one optimization iteration (or one scenario decision step).
- virtual bool pause ()=0

  Pauses an active optimization execution.
- virtual bool resume ()=0

  Resumes optimization execution after a pause.
- virtual bool stop ()=0

  Stops optimization execution and finalizes current run.
- virtual ExecutionState getExecutionState () const =0

  Returns current lifecycle state of the optimizer.
- virtual unsigned int getCurrentIteration () const =0

  Returns the number of optimization iterations already performed.
- virtual unsigned int getTotalSimulations () const =0

  Returns total number of simulated scenarios evaluated so far.
- virtual List< SolutionSummary > * getBestSolutions () const =0

  Returns all feasible solutions retained as "best" by the algorithm.
- virtual const SolutionSummary * getCurrentBestSolution () const =0

  Returns the best-known feasible solution, or nullptr when absent.
- virtual void resetResults ()=0

  Clears results from previous runs while preserving configuration.

17.530.1 Detailed Description

Interface for simulation-based optimization engines (OptQuest-like).
This contract defines how an optimization tool can be attached to a model, configured, and executed while managing:

- decision variables (selected SimulationControl objects),
- observed KPIs (selected SimulationResponse objects),
- objectives (minimize/maximize expressions), and
- constraints (boolean expressions evaluated as false==0 and true!=0).

Typical flow: 1) Associate a model (from file or direct instance). 2) Select controls and responses participating in the search. 3) Register optimization objectives and feasibility constraints. 4) Configure search parameters (iterations, retained best solutions, etc.). 5) Run lifecycle commands (start/step/pause/resume/stop). 6) Query current status, best solutions and progress metrics.

17.530.2 Member Function Documentation

17.530.2.1 addConstraint()

```
virtual void Optimizer_if::addConstraint (
            const ConstraintDefinition & constraint )  [pure virtual]
```

Adds one feasibility constraint expression.
Implemented in OptimizerDefaultImpl1.

17.530.2.2 addObjective()

```
virtual void Optimizer_if::addObjective (
            const ObjectiveDefinition & objective )  [pure virtual]
```

Adds one objective to the optimization model.
Implemented in OptimizerDefaultImpl1.

17.530.2.3 checkReady()

```
virtual bool Optimizer_if::checkReady (
            std::string * message = nullptr ) const  [pure virtual]
```

Validates readiness before running optimization.

Parameters

message	Receives validation details when non-null.

Returns

true when optimizer has enough data/configuration to start.

Implemented in OptimizerDefaultImpl1.

17.530.2.4 clearConstraints()

```
virtual void Optimizer_if::clearConstraints ( )  [pure virtual]
```

Clears all configured constraints.
Implemented in OptimizerDefaultImpl1.

17.530.2.5 clearObjectives()

```
virtual void Optimizer_if::clearObjectives ( )  [pure virtual]
```

Clears all configured objectives.
Implemented in OptimizerDefaultImpl1.

17.530.2.6 getAvailableControls()

```
virtual List< SimulationControl * > * Optimizer_if::getAvailableControls ( ) const  [pure
virtual]
```

Retrieves available model controls discoverable from Model.
Implemented in OptimizerDefaultImpl1.

17.530.2.7 getAvailableResponses()

```
virtual List< SimulationResponse * > * Optimizer_if::getAvailableResponses ( ) const  [pure
virtual]
```

Retrieves available model responses discoverable from Model.
Implemented in OptimizerDefaultImpl1.

17.530.2.8 getBestSolutions()

```
virtual List< SolutionSummary > * Optimizer_if::getBestSolutions ( ) const  [pure virtual]
```

Returns all feasible solutions retained as "best" by the algorithm.
Implemented in OptimizerDefaultImpl1.

17.530.2.9 getConstraints()

```
virtual List< ConstraintDefinition > * Optimizer_if::getConstraints ( ) const  [pure virtual]
```

Returns all configured feasibility constraints.
Implemented in OptimizerDefaultImpl1.

17.530.2.10 getCurrentBestSolution()

```
virtual const SolutionSummary * Optimizer_if::getCurrentBestSolution ( ) const  [pure virtual]
```

Returns the best-known feasible solution, or nullptr when absent.
Implemented in OptimizerDefaultImpl1.

17.530.2.11 getCurrentIteration()

```
virtual unsigned int Optimizer_if::getCurrentIteration ( ) const  [pure virtual]
```

Returns the number of optimization iterations already performed.
Implemented in OptimizerDefaultImpl1.

17.530.2.12 getExecutionState()

```
virtual ExecutionState Optimizer_if::getExecutionState ( ) const  [pure virtual]
```

Returns current lifecycle state of the optimizer.
Implemented in OptimizerDefaultImpl1.

17.530.2.13 getModel()

```
virtual Model * Optimizer_if::getModel ( ) const  [pure virtual]
```

Returns the model currently associated with the optimizer.
Implemented in OptimizerDefaultImpl1.

17.530.2.14 getModelFilename()

```
virtual std::string Optimizer_if::getModelFilename ( ) const  [pure virtual]
```

Returns the source filename previously configured for model loading.
Implemented in OptimizerDefaultImpl1.

17.530.2.15 getObjectives()

```
virtual List< ObjectiveDefinition > * Optimizer_if::getObjectives ( ) const  [pure virtual]
```

Returns all configured optimization objectives.
Implemented in OptimizerDefaultImpl1.

17.530.2.16 getSelectedControls()

```
virtual List< SimulationControl * > * Optimizer_if::getSelectedControls ( ) const  [pure virtual]
```

Returns currently selected controls used as decision variables.
Implemented in OptimizerDefaultImpl1.

17.530.2.17 getSelectedResponses()

```
virtual List< SimulationResponse * > * Optimizer_if::getSelectedResponses ( ) const  [pure
virtual]
```

Returns currently selected responses monitored by optimization.
Implemented in OptimizerDefaultImpl1.

17.530.2.18 getSettings()

```
virtual OptimizationSettings Optimizer_if::getSettings ( ) const  [pure virtual]
```

Returns currently active optimization settings.
Implemented in OptimizerDefaultImpl1.

17.530.2.19 getTotalSimulations()

```
virtual unsigned int Optimizer_if::getTotalSimulations ( ) const  [pure virtual]
```

Returns total number of simulated scenarios evaluated so far.
Implemented in OptimizerDefaultImpl1.

17.530.2.20 pause()

```
virtual bool Optimizer_if::pause ( )  [pure virtual]
```

Pauses an active optimization execution.
Implemented in OptimizerDefaultImpl1.

17.530.2.21 resetResults()

```
virtual void Optimizer_if::resetResults ( )  [pure virtual]
```

Clears results from previous runs while preserving configuration.
Implemented in OptimizerDefaultImpl1.

17.530.2.22 resume()

```
virtual bool Optimizer_if::resume ( )  [pure virtual]
```

Resumes optimization execution after a pause.
Implemented in OptimizerDefaultImpl1.

17.530.2.23 setModel()

```
virtual void Optimizer_if::setModel (
            Model * model )  [pure virtual]
```

Associates an already instantiated model with this optimizer.
Implemented in OptimizerDefaultImpl1.

17.530.2.24 setModelFilename()

```
virtual bool Optimizer_if::setModelFilename (
            const std::string & filename )  [pure virtual]
```

Loads/associates a model from a file supported by the simulator.

Parameters

filename	Model file path.

Returns

true when the model file was successfully loaded and linked.

Implemented in OptimizerDefaultImpl1.

17.530.2.25 setSelectedControls()

```
virtual void Optimizer_if::setSelectedControls (
            List< SimulationControl * > * controls )  [pure virtual]
```

Replaces the set of controls selected for optimization.
Implemented in OptimizerDefaultImpl1.

17.530.2.26 setSelectedResponses()

```
virtual void Optimizer_if::setSelectedResponses (
            List< SimulationResponse * > * responses )  [pure virtual]
```

Replaces the set of responses selected for optimization.
Implemented in OptimizerDefaultImpl1.

17.530.2.27 setSettings()

```
virtual void Optimizer_if::setSettings (
            const OptimizationSettings & settings )  [pure virtual]
```

Applies algorithm settings such as iteration and retention limits.
Implemented in OptimizerDefaultImpl1.

17.530.2.28 start()

```
virtual bool Optimizer_if::start ( )  [pure virtual]
```

Starts a new optimization run.

Returns

true on successful transition to RUNNING state.

Implemented in OptimizerDefaultImpl1.

17.530.2.29 step()

```
virtual bool Optimizer_if::step ( )  [pure virtual]
```

Executes one optimization iteration (or one scenario decision step).

Returns

true when a step was executed.

Implemented in OptimizerDefaultImpl1.

17.530.2.30 stop()

```
virtual bool Optimizer_if::stop ( )  [pure virtual]
```

Stops optimization execution and finalizes current run.
Implemented in OptimizerDefaultImpl1.

  Retrieves available model controls discoverable from Model.
- virtual List< SimulationResponse * > * getAvailableResponses () const override

  Retrieves available model responses discoverable from Model.
- virtual void setSelectedControls (List< SimulationControl * > *controls) override

  Replaces the set of controls selected for optimization.
- virtual void setSelectedResponses (List< SimulationResponse * > *responses) override

  Replaces the set of responses selected for optimization.
- virtual List< SimulationControl * > * getSelectedControls () const override

  Returns currently selected controls used as decision variables.
- virtual List< SimulationResponse * > * getSelectedResponses () const override

  Returns currently selected responses monitored by optimization.
- virtual void addObjective (const ObjectiveDefinition &objective) override

  Adds one objective to the optimization model.
- virtual void clearObjectives () override

  Clears all configured objectives.
- virtual List< ObjectiveDefinition > * getObjectives () const override

  Returns all configured optimization objectives.
- virtual void addConstraint (const ConstraintDefinition &constraint) override

  Adds one feasibility constraint expression.
- virtual void clearConstraints () override

  Clears all configured constraints.
- virtual List< ConstraintDefinition > * getConstraints () const override

Returns all configured feasibility constraints.

- virtual void setSettings (const OptimizationSettings &settings) override

  Applies algorithm settings such as iteration and retention limits.
- virtual OptimizationSettings getSettings () const override

  Returns currently active optimization settings.
- virtual bool checkReady (std::string *message=nullptr) const override

  Validates readiness before running optimization.
- virtual bool start () override

  Starts a new optimization run.
- virtual bool step () override

  Executes one optimization iteration (or one scenario decision step).
- virtual bool pause () override

  Pauses an active optimization execution.
- virtual bool resume () override

  Resumes optimization execution after a pause.
- virtual bool stop () override

  Stops optimization execution and finalizes current run.
- virtual ExecutionState getExecutionState () const override

  Returns current lifecycle state of the optimizer.
- virtual unsigned int getCurrentIteration () const override

  Returns the number of optimization iterations already performed.
- virtual unsigned int getTotalSimulations () const override

  Returns total number of simulated scenarios evaluated so far.
- virtual List< SolutionSummary > * getBestSolutions () const override

  Returns all feasible solutions retained as "best" by the algorithm.
- virtual const SolutionSummary * getCurrentBestSolution () const override

  Returns the best-known feasible solution, or nullptr when absent.
- virtual void resetResults () override

  Clears results from previous runs while preserving configuration.

Additional Inherited Members

Public Types inherited from Optimizer_if

- enum class ObjectiveSense { **MINIMIZE** , **MAXIMIZE** }

  Direction used by an optimization objective.
- enum class ExecutionState {
  NOT_READY , **READY** , **RUNNING** , **PAUSED** ,
  STOPPED , **FINISHED** , **ERROR** }

  Execution state of the optimization process.

17.531.1 Detailed Description

Initial concrete scaffold for an OptQuest-like optimizer.
This class intentionally provides only the public API declaration for the first default implementation.
Current status:

- interface contract declared;
- behavior/algorithm implementation intentionally deferred.

Planned behavior:

- discover controls/responses from an associated model,
- evaluate objective and constraint expressions through parser context,
- execute iterative search preserving top feasible solutions.

17.531.2 Member Function Documentation

17.531.2.1 addConstraint()

```
void OptimizerDefaultImpl1::addConstraint (
            const ConstraintDefinition & constraint )  [override], [virtual]
```

Adds one feasibility constraint expression.
Implements Optimizer_if.

17.531.2.2 addObjective()

```
void OptimizerDefaultImpl1::addObjective (
            const ObjectiveDefinition & objective )  [override], [virtual]
```

Adds one objective to the optimization model.
Implements Optimizer_if.

17.531.2.3 checkReady()

```
bool OptimizerDefaultImpl1::checkReady (
            std::string * message = nullptr ) const  [override], [virtual]
```

Validates readiness before running optimization.

Parameters

message	Receives validation details when non-null.

Returns

true when optimizer has enough data/configuration to start.

Implements Optimizer_if.

17.531.2.4 clearConstraints()

```
void OptimizerDefaultImpl1::clearConstraints ( )  [override], [virtual]
```

Clears all configured constraints.
Implements Optimizer_if.

17.531.2.5 clearObjectives()

```
void OptimizerDefaultImpl1::clearObjectives ( )  [override], [virtual]
```

Clears all configured objectives.
Implements Optimizer_if.

17.531.2.6 getAvailableControls()

```
List< SimulationControl * > * OptimizerDefaultImpl1::getAvailableControls ( ) const  [override],
[virtual]
```

Retrieves available model controls discoverable from Model.
Implements Optimizer_if.

17.531.2.7 getAvailableResponses()

```
List< SimulationResponse * > * OptimizerDefaultImpl1::getAvailableResponses ( ) const  [override],
[virtual]
```

Retrieves available model responses discoverable from Model.
Implements Optimizer_if.

17.531.2.8 getBestSolutions()

`List< Optimizer_if::SolutionSummary > * OptimizerDefaultImpl1::getBestSolutions ( ) const [override], [virtual]`
Returns all feasible solutions retained as "best" by the algorithm.
Implements Optimizer_if.

17.531.2.9 getConstraints()

`List< Optimizer_if::ConstraintDefinition > * OptimizerDefaultImpl1::getConstraints ( ) const [override], [virtual]`
Returns all configured feasibility constraints.
Implements Optimizer_if.

17.531.2.10 getCurrentBestSolution()

`const Optimizer_if::SolutionSummary * OptimizerDefaultImpl1::getCurrentBestSolution ( ) const [override], [virtual]`
Returns the best-known feasible solution, or nullptr when absent.
Implements Optimizer_if.

17.531.2.11 getCurrentIteration()

`unsigned int OptimizerDefaultImpl1::getCurrentIteration ( ) const [override], [virtual]`
Returns the number of optimization iterations already performed.
Implements Optimizer_if.

17.531.2.12 getExecutionState()

`Optimizer_if::ExecutionState OptimizerDefaultImpl1::getExecutionState ( ) const [override], [virtual]`
Returns current lifecycle state of the optimizer.
Implements Optimizer_if.

17.531.2.13 getModel()

`Model * OptimizerDefaultImpl1::getModel ( ) const [override], [virtual]`
Returns the model currently associated with the optimizer.
Implements Optimizer_if.

17.531.2.14 getModelFilename()

`std::string OptimizerDefaultImpl1::getModelFilename ( ) const [override], [virtual]`
Returns the source filename previously configured for model loading.
Implements Optimizer_if.

17.531.2.15 getObjectives()

`List< Optimizer_if::ObjectiveDefinition > * OptimizerDefaultImpl1::getObjectives ( ) const [override], [virtual]`
Returns all configured optimization objectives.
Implements Optimizer_if.

17.531.2.16 getSelectedControls()

`List< SimulationControl * > * OptimizerDefaultImpl1::getSelectedControls ( ) const [override], [virtual]`
Returns currently selected controls used as decision variables.
Implements Optimizer_if.

17.531.2.17 getSelectedResponses()

```
List< SimulationResponse * > * OptimizerDefaultImpl1::getSelectedResponses ( ) const  [override], [virtual]
```

Returns currently selected responses monitored by optimization.
Implements Optimizer_if.

17.531.2.18 getSettings()

```
Optimizer_if::OptimizationSettings OptimizerDefaultImpl1::getSettings ( ) const  [override], [virtual]
```

Returns currently active optimization settings.
Implements Optimizer_if.

17.531.2.19 getTotalSimulations()

```
unsigned int OptimizerDefaultImpl1::getTotalSimulations ( ) const  [override], [virtual]
```

Returns total number of simulated scenarios evaluated so far.
Implements Optimizer_if.

17.531.2.20 pause()

```
bool OptimizerDefaultImpl1::pause ( )  [override], [virtual]
```

Pauses an active optimization execution.
Implements Optimizer_if.

17.531.2.21 resetResults()

```
void OptimizerDefaultImpl1::resetResults ( )  [override], [virtual]
```

Clears results from previous runs while preserving configuration.
Implements Optimizer_if.

17.531.2.22 resume()

```
bool OptimizerDefaultImpl1::resume ( )  [override], [virtual]
```

Resumes optimization execution after a pause.
Implements Optimizer_if.

17.531.2.23 setModel()

```
void OptimizerDefaultImpl1::setModel (
            Model * model )  [override], [virtual]
```

Associates an already instantiated model with this optimizer.
Implements Optimizer_if.

17.531.2.24 setModelFilename()

```
bool OptimizerDefaultImpl1::setModelFilename (
            const std::string & filename )  [override], [virtual]
```

Loads/associates a model from a file supported by the simulator.

Parameters

filename	Model file path.

Returns

true when the model file was successfully loaded and linked.

Implements Optimizer_if.

17.531.2.25 setSelectedControls()

```
void OptimizerDefaultImpl1::setSelectedControls (
            List< SimulationControl * > * controls )  [override], [virtual]
```

Replaces the set of controls selected for optimization.
Implements Optimizer_if.

17.531.2.26 setSelectedResponses()

```
void OptimizerDefaultImpl1::setSelectedResponses (
            List< SimulationResponse * > * responses )  [override], [virtual]
```

Replaces the set of responses selected for optimization.
Implements Optimizer_if.

17.531.2.27 setSettings()

```
void OptimizerDefaultImpl1::setSettings (
            const OptimizationSettings & settings )  [override], [virtual]
```

Applies algorithm settings such as iteration and retention limits.
Implements Optimizer_if.

17.531.2.28 start()

```
bool OptimizerDefaultImpl1::start ( )  [override], [virtual]
```

Starts a new optimization run.

Returns

true on successful transition to RUNNING state.

Implements Optimizer_if.

17.531.2.29 step()

```
bool OptimizerDefaultImpl1::step ( )  [override], [virtual]
```

Executes one optimization iteration (or one scenario decision step).

Returns

true when a step was executed.

Implements Optimizer_if.

17.531.2.30 stop()

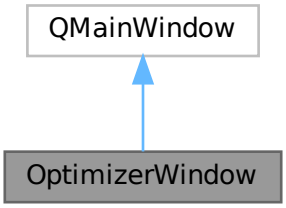
```
bool OptimizerDefaultImpl1::stop ( )  [override], [virtual]
```

Stops optimization execution and finalizes current run.
Implements Optimizer_if.
The documentation for this class was generated from the following files:

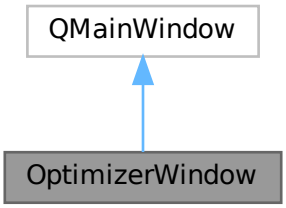
- tools/Optimization/OptimizerDefaultImpl1.h
- tools/Optimization/OptimizerDefaultImpl1.cpp

17.532 OptimizerWindow Class Reference

Inheritance diagram for OptimizerWindow:



Collaboration diagram for OptimizerWindow:



Classes

- class ProgressPlot

Public Member Functions

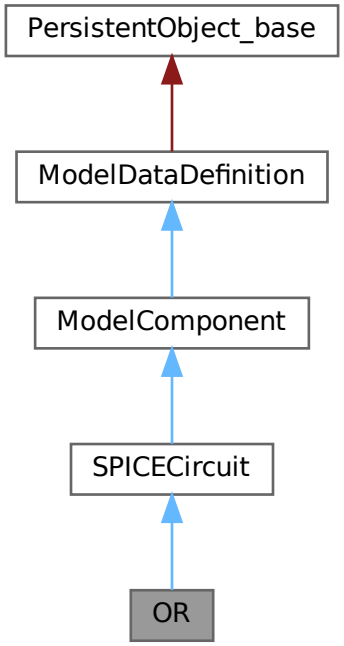
- **OptimizerWindow** (Simulator ∗simulator, QWidget ∗parent=nullptr)

The documentation for this class was generated from the following files:

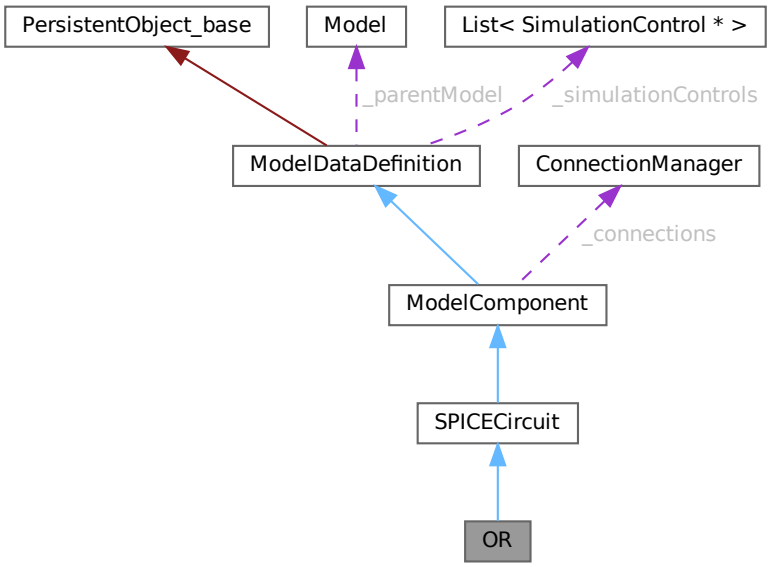
- applications/gui/genesys/tools/optimizer/OptimizerWindow.h
- applications/gui/genesys/tools/optimizer/OptimizerWindow.cpp

17.533 OR Class Reference

Inheritance diagram for OR:



Collaboration diagram for OR:



Public Member Functions

- **OR** (Model *model, std::string name="")
- void Build () override
- void **setPMOSWidth** (float PMOSWidth)
- void **setPMOSLength** (float length)
- void **setNMOSWidth** (float NMOSWidth)
- void **setNMOSLength** (float NMOSLength)
- void **setElectricalModel** (std::string electricalModel)

Public Member Functions inherited from SPICECircuit

- **SPICECircuit** (Model *model, std::string name="")

  constructors
- void **setRunner** (SPICERunner *runner)

  new public user methods for this components
- SPICERunner * **getRunner** ()
- virtual std::string show () override

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

Updates the user-visible label of this instance.

- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from SPICECircuit

- static PluginInformation * **GetPluginInformation** ()

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")
- static std::vector< std::string > **split** (std::string word, char split_char)

  Externalize function GetPluginInformation to be accessible throught dynamic linked library.

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.

Protected Member Functions inherited from SPICECircuit

- void **BuildCircuit** (std::string description, unsigned int id, std::vector< std::string > the_params={""}, std::string the_model="", std::string the_model_file="")

  virtual protected method that must be overriden
- void **UpdateConnections** ()
- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  This method is only for ModelComponents, not ModelDataElements.
- virtual void _createNonEditableDataDefinitions () override

  virtual protected methods that could be overriden by derived classes, if needed

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual bool _check (std::string &errorMessage)

  could be overriden by derived classes
- virtual ParserChangesInformation * _getParserChangesInformation ()

17.533.1 Member Function Documentation

17.533.1.1 _loadInstance()

```
bool OR::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from SPICECircuit.

17.533.1.2 _saveInstance()

```
void OR::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from SPICECircuit.

17.533.1.3 Build()

```
void OR::Build ( )  [override], [virtual]
```

Reimplemented from SPICECircuit.

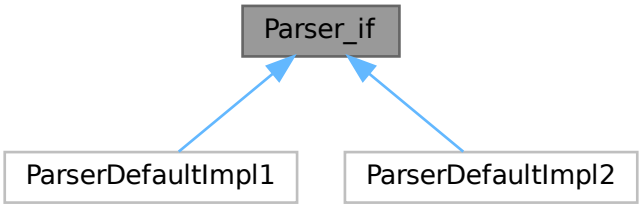
17.544 Parser_if Class Reference

Interface for evaluating model expressions and stochastic functions.
`#include <kernel/simulator/Parser_if.h>`
Inheritance diagram for Parser_if:



Public Member Functions

- virtual double parse (const std::string expression)=0

  parse
- virtual double parse (const std::string expression, bool &success, std::string &errorMessage)=0

  parse
- virtual std::string getErrorMessage ()=0

  getErrorMessage
- virtual void setSampler (Sampler_if *sampler)=0

  Sets the sampler used by stochastic language functions.
- virtual Sampler_if * getSampler () const =0

  Returns the sampler currently associated with the parser.
- virtual genesyspp_driver getParser () const =0

  getParser

17.544.1 Detailed Description

Interface for evaluating model expressions and stochastic functions.
Parser implementations are used by model components/data definitions to evaluate arithmetic/logical expressions, integrating deterministic symbols and stochastic calls backed by a `Sampler_if` instance.

17.544.2 Member Function Documentation

17.544.2.1 getErrorMessage()

```
virtual std::string Parser_if::getErrorMessage ( )  [pure virtual]
```

getErrorMessage

Returns

Returns the last error message produced by the parser.
Implemented in ParserDefaultImpl1, and ParserDefaultImpl2.

17.544.2.2 getParser()

```
virtual genesyspp_driver Parser_if::getParser ( ) const  [pure virtual]
```

getParser

Returns

Exposes the internal parser driver for advanced integration scenarios.
Implemented in ParserDefaultImpl2.

17.544.2.3 getSampler()

```
virtual Sampler_if * Parser_if::getSampler ( ) const  [pure virtual]
```

Returns the sampler currently associated with the parser.
The returned pointer is non-owning. Callers must consult concrete parser documentation for lifetime/ownership details of the underlying instance.
Implemented in ParserDefaultImpl2.

17.544.2.4 parse() [1/2]

```
virtual double Parser_if::parse (
            const std::string expression )  [pure virtual]
```

parse

Parameters

expression	

Returns

Evaluates an expression and returns its numeric value; may throw on syntax/semantic errors.
Implemented in ParserDefaultImpl1, and ParserDefaultImpl2.

17.544.2.5 parse() [2/2]

```
virtual double Parser_if::parse (
            const std::string expression,
            bool & success,
            std::string & errorMessage )  [pure virtual]
```

parse

Parameters

expression	

Parameters

success	
errorMessage	

Returns

Evaluates an expression without throwing and reports status via output parameters.
Implemented in ParserDefaultImpl1, and ParserDefaultImpl2.

17.544.2.6 setSampler()

```
virtual void Parser_if::setSampler (
            Sampler_if * sampler )  [pure virtual]
```

Sets the sampler used by stochastic language functions.

Parameters

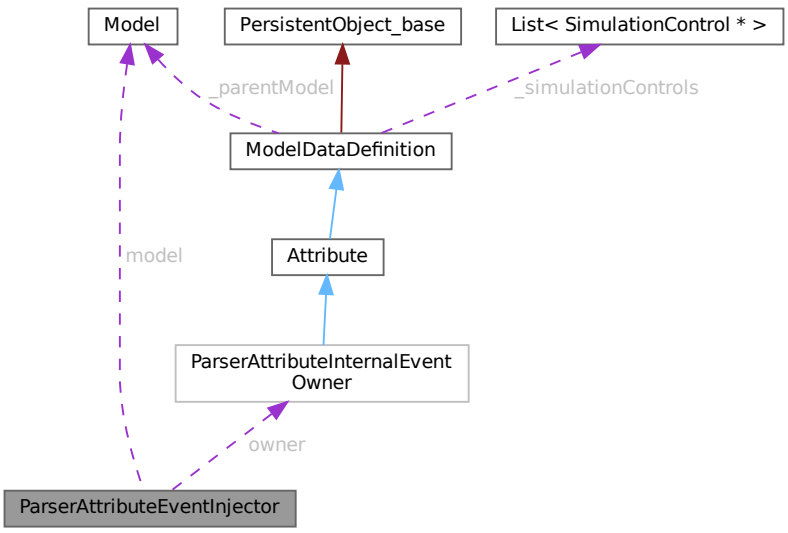
sampler	Pointer to sampler instance that must outlive parser usage unless an implementation-specific ownership transfer is explicitly documented.

This interface does not enforce ownership transfer. Concrete parser implementations may own a sampler created/provided at construction time, but samplers passed through `setSampler` are expected to be externally owned by default unless documented otherwise by the implementation.
Implemented in ParserDefaultImpl2.
The documentation for this class was generated from the following file:

- kernel/simulator/Parser_if.h

17.545 ParserAttributeEventInjector Struct Reference

Collaboration diagram for ParserAttributeEventInjector:



Public Member Functions

- void **OnReplicationStart** (SimulationEvent ∗)

Public Attributes

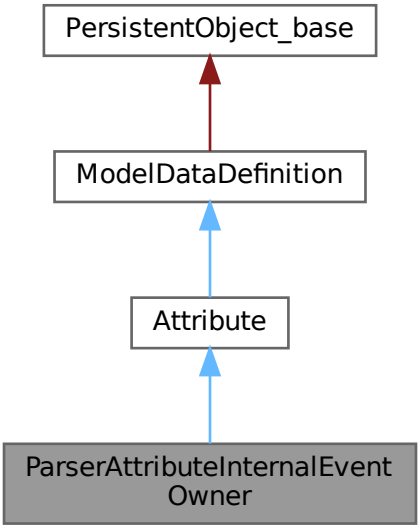
- Model ∗ **model** = nullptr
- ParserAttributeInternalEventOwner ∗ **owner** = nullptr
- std::string **attributeName** = "ParserAttrND"
- bool **inserted** = false

The documentation for this struct was generated from the following file:

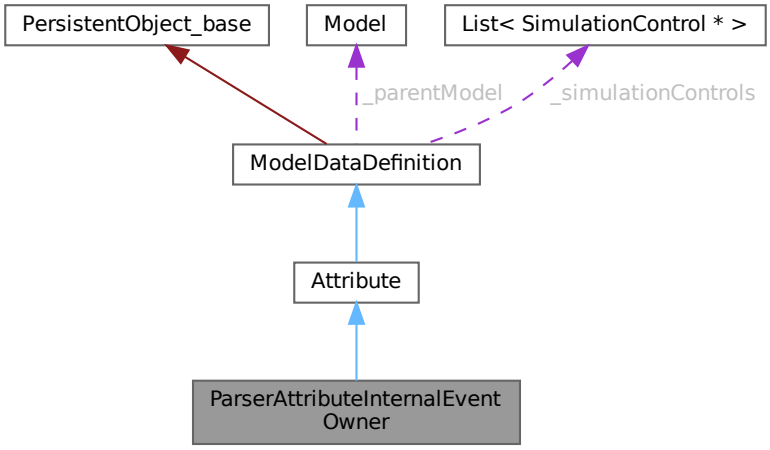
- tests/unit/test_parser_expressions.cpp

17.546 ParserAttributeInternalEventOwner Class Reference

Inheritance diagram for ParserAttributeInternalEventOwner:



Collaboration diagram for ParserAttributeInternalEventOwner:



Public Member Functions

- **ParserAttributeInternalEventOwner** (Model *model, const std::string &name="")
- void **Noop** (void *)

Public Member Functions inherited from Attribute

- **Attribute** (Model *model, std::string name="", std::string dataDefinitionTypename=Util::TypeOf< Attribute >())

  Creates an entity attribute definition in the model.
- virtual ~**Attribute** () override

  Releases sparse initial values owned by this definition.
- virtual std::string show () override

  Returns a textual representation of this data definition.
- virtual std::string getInitialValuesText () const

  Returns the initial values serialized in bracket notation.
- virtual void setInitialValuesText (std::string valuesText)

  Parses bracket notation and replaces the initial value store.
- double **getInitialValue** (std::string index="")

  Reads the initial sparse value, returning 0.0 when the index is absent.
- void **setInitialValue** (double value, std::string index="")

  Writes the initial sparse value at the scalar or indexed position.
- void **setInitialValues** (const std::vector< std::pair< std::string, double > > values)

  Replaces/extends initial sparse values from textual index/value pairs.
- void **copyInitialValuesFrom** (const Attribute &source)

  Copies the full initial sparse store from another attribute.
- void **insertDimentionSize** (unsigned int size)

  Appends one dimension size to the attribute definition.
- std::list< unsigned int > * **getDimensionSizes** () const

  Returns dimension sizes for compatibility with existing callers.
- std::map< std::string, double > * **getInitialValues** () const

  Returns mutable initial sparse values for compatibility with existing callers.

- SparseValueStore * **getInitialValueStore** ()

  Returns the sparse initial value store used by this attribute.
- bool **isInitialValuesTextValid** () const

  Returns whether the last textual initial value is syntactically valid.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.

- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Additional Inherited Members

Static Public Member Functions inherited from Attribute

- static PluginInformation * **GetPluginInformation** ()
- static ModelDataDefinition * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions inherited from Attribute

- virtual bool _loadInstance (PersistenceRecord *fields) override

  must be overriden by derived classes
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual ParserChangesInformation * _getParserChangesInformation ()
- virtual void _initBetweenReplications ()
- virtual void _addSimulationControl (SimulationControl *control)
- virtual void _createInternalAndAttachedData ()

- virtual std::string getErrorMessage () override

  getErrorMessage

Public Member Functions inherited from Parser_if

- virtual void setSampler (Sampler_if ∗sampler)=0

  Sets the sampler used by stochastic language functions.
- virtual Sampler_if ∗ getSampler () const =0

  Returns the sampler currently associated with the parser.
- virtual genesyspp_driver getParser () const =0

  getParser

17.549.1 Member Function Documentation

17.549.1.1 getErrorMessage()

```
std::string ParserDefaultImpl1::getErrorMessage ( )  [override], [virtual]
```

getErrorMessage

Returns

Returns the last error message produced by the parser.
Implements Parser_if.

17.549.1.2 parse() [1/2]

```
double ParserDefaultImpl1::parse (
            const std::string expression )  [override], [virtual]
```

parse

Parameters

expression	

Returns

Evaluates an expression and returns its numeric value; may throw on syntax/semantic errors.
Implements Parser_if.

17.549.1.3 parse() [2/2]

```
double ParserDefaultImpl1::parse (
            const std::string expression,
            bool & success,
            std::string & errorMessage )  [override], [virtual]
```

parse

Parameters

expression	
success	
errorMessage	

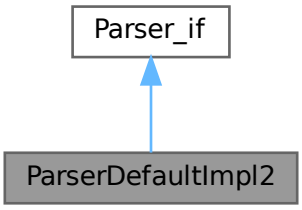
Returns

Evaluates an expression without throwing and reports status via output parameters.
Implements Parser_if.
The documentation for this class was generated from the following files:

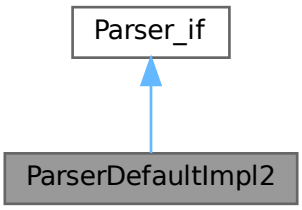
- kernel/simulator/ParserDefaultImpl1.h
- kernel/simulator/ParserDefaultImpl1.cpp

17.550 ParserDefaultImpl2 Class Reference

Inheritance diagram for ParserDefaultImpl2:



Collaboration diagram for ParserDefaultImpl2:



Public Member Functions

- ParserDefaultImpl2 (Model ∗model, Sampler_if ∗sampler, bool throws=false)

  Creates parser wrapper bound to a model and an initial sampler.
- virtual ∼ParserDefaultImpl2 ()

  Destroys parser wrapper and releases only parser-owned sampler.
- virtual double parse (const std::string expression) override

  parse
- virtual double parse (const std::string expression, bool &success, std::string &errorMessage) override

  parse
- virtual std::string getErrorMessage () override

getErrorMessage

- virtual void setSampler (Sampler_if ∗_sampler) override

  Replaces parser sampler with an externally-owned sampler.

- virtual Sampler_if ∗ getSampler () const override

  Returns the sampler currently associated with the parser.

- virtual genesyspp_driver getParser () const override

  getParser

17.550.1 Constructor & Destructor Documentation

17.550.1.1 ParserDefaultImpl2()

```
ParserDefaultImpl2::ParserDefaultImpl2 (
            Model * model,
            Sampler_if * sampler,
            bool throws = false )
```

Creates parser wrapper bound to a model and an initial sampler.
The constructor stores `sampler` in the internal driver and marks it as parser-owned when non-null. This preserves current model behavior where the parser starts with an internally managed sampler instance.

17.550.1.2 ∼ParserDefaultImpl2()

```
ParserDefaultImpl2::~ParserDefaultImpl2 ( )  [virtual]
```

Destroys parser wrapper and releases only parser-owned sampler.
The destructor deletes the current sampler only when ownership is flagged as internal. Samplers installed through setSampler(...) are non-owned by default and therefore not deleted at destruction time.

17.550.2 Member Function Documentation

17.550.2.1 getErrorMessage()

```
std::string ParserDefaultImpl2::getErrorMessage ( )  [override], [virtual]
```

getErrorMessage

Returns

Returns the last error message produced by the parser.
Implements Parser_if.

17.550.2.2 getParser()

```
genesyspp_driver ParserDefaultImpl2::getParser ( ) const  [override], [virtual]
```

getParser

Returns

Exposes the internal parser driver for advanced integration scenarios.
Implements Parser_if.

17.550.2.3 getSampler()

```
Sampler_if * ParserDefaultImpl2::getSampler ( ) const  [override], [virtual]
```

Returns the sampler currently associated with the parser.
The returned pointer is non-owning. Callers must consult concrete parser documentation for lifetime/ownership details of the underlying instance.
Implements Parser_if.

17.550.2.4 parse() [1/2]

```
double ParserDefaultImpl2::parse (
            const std::string expression )  [override], [virtual]
```

parse

Parameters

expression	

Returns

Evaluates an expression and returns its numeric value; may throw on syntax/semantic errors.
Implements Parser_if.

17.550.2.5 parse() [2/2]

```
double ParserDefaultImpl2::parse (
            const std::string expression,
            bool & success,
            std::string & errorMessage )  [override], [virtual]
```

parse

Parameters

expression	
success	
errorMessage	

Returns

Evaluates an expression without throwing and reports status via output parameters.
Implements Parser_if.

17.550.2.6 setSampler()

```
void ParserDefaultImpl2::setSampler (
            Sampler_if * _sampler )  [override], [virtual]
```

Replaces parser sampler with an externally-owned sampler.
If the parser currently owns a previous sampler, that previous sampler is released before binding the new pointer.
The provided sampler pointer is then tracked as non-owned.
Implements Parser_if.
The documentation for this class was generated from the following files:

- kernel/simulator/ParserDefaultImpl2.h
- kernel/simulator/ParserDefaultImpl2.cpp

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.

- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes
- virtual void _initBetweenReplications () override
- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual void _createEditableDataDefinitions () override

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual ParserChangesInformation * _getParserChangesInformation ()

17.554.1 Detailed Description

Applies sustained pathway-collapse responses to a whole-cell state.
PathwayStressResponseComponent watches one pathway activity proxy already stored in WholeCellState and converts repeated low-activity windows into higher-level lifecycle responses such as arrest and death.
The component is intentionally simple:

- it does not solve metabolism;
- it does not schedule time;
- it does not route entities.

Instead, it acts as a dedicated biological stress-response layer that can be placed between checkpointing and fate-routing components in hybrid whole-cell examples.

17.554.2 Member Function Documentation

17.554.2.1 _check()

```
bool PathwayStressResponseComponent::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.554.2.2 _createEditableDataDefinitions()

```
void PathwayStressResponseComponent::_createEditableDataDefinitions ( )  [override], [protected],
[virtual]
```

Reimplemented from ModelDataDefinition.

17.554.2.3 _initBetweenReplications()

```
void PathwayStressResponseComponent::_initBetweenReplications ( )  [override], [protected],
[virtual]
```

Reimplemented from ModelDataDefinition.

17.554.2.4 _loadInstance()

```
bool PathwayStressResponseComponent::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.554.2.5 _onDispatchEvent()

```
void PathwayStressResponseComponent::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.554.2.6 _saveInstance()

```
void PathwayStressResponseComponent::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.554.2.7 show()

```
std::string PathwayStressResponseComponent::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

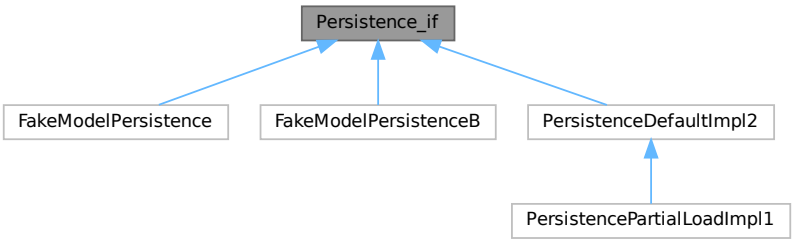
Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

- plugins/components/WholeCellModeling/PathwayStressResponseComponent.h
- plugins/components/WholeCellModeling/PathwayStressResponseComponent.cpp

17.555 Persistence_if Class Reference

Interface for model serialization/deserialization services.
`#include <kernel/simulator/persistence/Persistence_if.h>`

Inheritance diagram for Persistence_if:



Public Types

- enum class **Options** : int {
  SAVEDEFAULTS = 1 , **HIDEIDKEY** = 2 , **HIDETYPEKEY** = 4 , **HIDENAMEKEY** = 8 ,
  SORTALPHLY = 16 }

Public Member Functions

- virtual bool save (std::string filename)=0

  Serializes and saves the model to the provided filename.
- virtual bool load (std::string filename)=0

  Loads and deserializes a model from file.
- virtual bool hasChanged ()=0

  Indicates whether persistent state changed since the last save/load.
- virtual void setHasChanged (bool hasChanged)=0

  Updates the persistent-state changed flag.
- virtual bool getOption (Persistence_if::Options option)=0

  Returns whether a persistence option is currently enabled.
- virtual void setOption (Persistence_if::Options option, bool value)=0

  Enables or disables a persistence option.
- virtual std::string getFormatedField (PersistenceRecord *fields)=0

  Formats a set of fields as text according to the persistence format.

17.555.1 Detailed Description

Interface for model serialization/deserialization services.
Persistence implementations convert in-memory model structures to/from external representations (e.g., GEN/↩ XML/JSON-like formats) and expose formatting/options hooks used by the kernel persistence pipeline.

17.555.2 Member Function Documentation

17.555.2.1 getFormatedField()

```
virtual std::string Persistence_if::getFormatedField (
            PersistenceRecord * fields ) [pure virtual]
```

Formats a set of fields as text according to the persistence format.
Implemented in FakeModelPersistence, FakeModelPersistenceB, and PersistenceDefaultImpl2.

17.555.2.2 getOption()

```
virtual bool Persistence_if::getOption (
            Persistence_if::Options option )  [pure virtual]
```

Returns whether a persistence option is currently enabled.
Implemented in PersistenceDefaultImpl2, FakeModelPersistence, and FakeModelPersistenceB.

17.555.2.3 hasChanged()

```
virtual bool Persistence_if::hasChanged ( )  [pure virtual]
```

Indicates whether persistent state changed since the last save/load.
Implemented in PersistenceDefaultImpl2, FakeModelPersistence, and FakeModelPersistenceB.

17.555.2.4 load()

```
virtual bool Persistence_if::load (
            std::string filename )  [pure virtual]
```

Loads and deserializes a model from file.
Implemented in PersistenceDefaultImpl2, PersistencePartialLoadImpl1, FakeModelPersistence, and FakeModelPersistenceB.

17.555.2.5 save()

```
virtual bool Persistence_if::save (
            std::string filename )  [pure virtual]
```

Serializes and saves the model to the provided filename.
Implemented in PersistenceDefaultImpl2, FakeModelPersistence, and FakeModelPersistenceB.

17.555.2.6 setHasChanged()

```
virtual void Persistence_if::setHasChanged (
            bool hasChanged )  [pure virtual]
```

Updates the persistent-state changed flag.
Implemented in PersistenceDefaultImpl2, FakeModelPersistence, and FakeModelPersistenceB.

17.555.2.7 setOption()

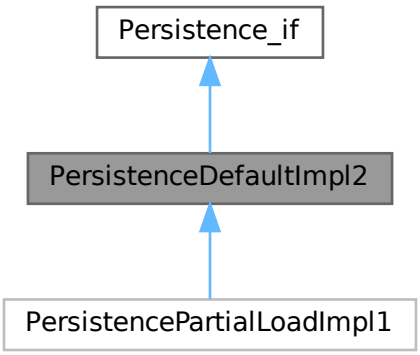
```
virtual void Persistence_if::setOption (
            Persistence_if::Options option,
            bool value )  [pure virtual]
```

Enables or disables a persistence option.
Implemented in PersistenceDefaultImpl2, FakeModelPersistence, and FakeModelPersistenceB.
The documentation for this class was generated from the following file:

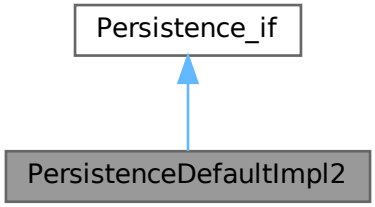
- kernel/simulator/persistence/Persistence_if.h

17.556 PersistenceDefaultImpl2 Class Reference

Inheritance diagram for PersistenceDefaultImpl2:



Collaboration diagram for PersistenceDefaultImpl2:



Public Member Functions

- **PersistenceDefaultImpl2** (Model *model)
- bool save (std::string filename) override

  Serializes and saves the model to the provided filename.
- bool load (std::string filename) override

  Loads and deserializes a model from file.
- bool hasChanged () override

  Indicates whether persistent state changed since the last save/load.
- void setHasChanged (bool hasChanged) override

  Updates the persistent-state changed flag.
- bool getOption (Persistence_if::Options option) override

  Returns whether a persistence option is currently enabled.
- void setOption (Persistence_if::Options option, bool value) override

  Enables or disables a persistence option.
- std::string getFormatedField (PersistenceRecord *fields) override

  Formats a set of fields as text according to the persistence format.

Additional Inherited Members

Public Types inherited from Persistence_if

- enum class **Options** : int {
  SAVEDEFAULTS = 1 , **HIDEIDKEY** = 2 , **HIDETYPEKEY** = 4 , **HIDENAMEKEY** = 8 ,
  SORTALPHLY = 16 }

17.556.1 Member Function Documentation

17.556.1.1 getFormatedField()

```
std::string PersistenceDefaultImpl2::getFormatedField (
            PersistenceRecord * fields )  [override], [virtual]
```

Formats a set of fields as text according to the persistence format.
Implements Persistence_if.

17.556.1.2 getOption()

```
bool PersistenceDefaultImpl2::getOption (
            Persistence_if::Options option )  [override], [virtual]
```

Returns whether a persistence option is currently enabled.
Implements Persistence_if.

17.556.1.3 hasChanged()

```
bool PersistenceDefaultImpl2::hasChanged ( )  [override], [virtual]
```

Indicates whether persistent state changed since the last save/load.
Implements Persistence_if.

17.556.1.4 load()

```
bool PersistenceDefaultImpl2::load (
            std::string filename )  [override], [virtual]
```

Loads and deserializes a model from file.
Implements Persistence_if.
Reimplemented in PersistencePartialLoadImpl1.

17.556.1.5 save()

```
bool PersistenceDefaultImpl2::save (
            std::string filename )  [override], [virtual]
```

Serializes and saves the model to the provided filename.
Implements Persistence_if.

17.556.1.6 setHasChanged()

```
void PersistenceDefaultImpl2::setHasChanged (
            bool hasChanged )  [override], [virtual]
```

Updates the persistent-state changed flag.
Implements Persistence_if.

17.556.1.7 setOption()

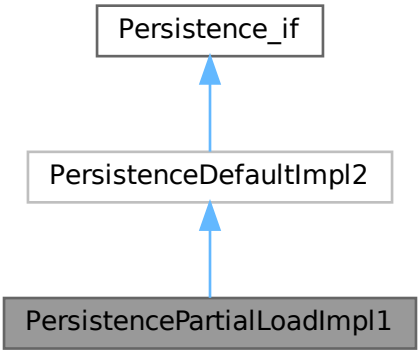
```
void PersistenceDefaultImpl2::setOption (
            Persistence_if::Options option,
            bool value )  [override], [virtual]
```

Enables or disables a persistence option.
Implements Persistence_if.
The documentation for this class was generated from the following files:

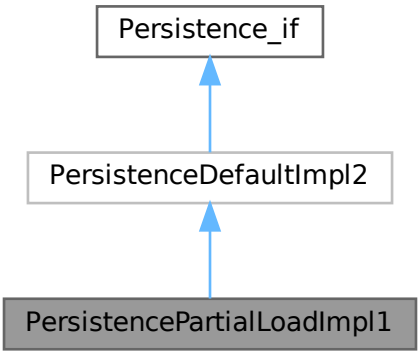
- kernel/simulator/persistence/PersistenceDefaultImpl2.h
- kernel/simulator/persistence/PersistenceDefaultImpl2.cpp

17.557 PersistencePartialLoadImpl1 Class Reference

Inheritance diagram for PersistencePartialLoadImpl1:



Collaboration diagram for PersistencePartialLoadImpl1:



Public Member Functions

- **PersistencePartialLoadImpl1** (Model *model)
- bool load (std::string filename) override

  Loads and deserializes a model from file.

Public Member Functions inherited from PersistenceDefaultImpl2

- **PersistenceDefaultImpl2** (Model *model)

- bool save (std::string filename) override

  Serializes and saves the model to the provided filename.
- bool hasChanged () override

  Indicates whether persistent state changed since the last save/load.
- void setHasChanged (bool hasChanged) override

  Updates the persistent-state changed flag.
- bool getOption (Persistence_if::Options option) override

  Returns whether a persistence option is currently enabled.
- void setOption (Persistence_if::Options option, bool value) override

  Enables or disables a persistence option.
- std::string getFormatedField (PersistenceRecord *fields) override

  Formats a set of fields as text according to the persistence format.

Additional Inherited Members

  SORTALPHLY = 16 }

17.557.1 Member Function Documentation

17.557.1.1 load()

```
bool PersistencePartialLoadImpl1::load (
            std::string filename )  [override], [virtual]
```

Loads and deserializes a model from file.
Reimplemented from PersistenceDefaultImpl2.
The documentation for this class was generated from the following files:

- kernel/simulator/persistence/PersistencePartialLoadImpl1.h
- kernel/simulator/persistence/PersistencePartialLoadImpl1.cpp

17.558 PersistenceRecord Class Reference

Serialization/Deserialization structure which behaves like an associative array.
`#include <kernel/simulator/Persistence.h>`

Classes

- struct Entry

  "Raw" entry, users should treat this as an opaque type since payloads could be in any format.

Public Types

- using **Payload** = std::string
- using **Iterator** = std::unordered_map< std::string, Entry >::iterator

Public Member Functions

- virtual PersistenceRecord * **newInstance** ()
- virtual std::string **loadField** (const std::string &key, const std::string &defaultValue="")
- virtual double **loadField** (const std::string &key, double defaultValue)
- virtual unsigned int **loadField** (const std::string &key, unsigned int defaultValue)
- virtual int **loadField** (const std::string &key, int defaultValue)
- virtual Util::TimeUnit **loadField** (const std::string &key, Util::TimeUnit defaultValue)

- virtual void **saveField** (const std::string &key, const std::string &value, const std::string &defaultValue, const bool saveIfDefault=false)
- virtual void **saveField** (const std::string &key, const std::string &value)
- virtual void **saveField** (const std::string &key, double value, const double defaultValue, const bool saveIf↩ Default=false)
- virtual void **saveField** (const std::string &key, unsigned int value, const unsigned int defaultValue, const bool saveIfDefault=false)
- virtual void **saveField** (const std::string &key, unsigned int value)
- virtual void **saveField** (const std::string &key, int value, const int defaultValue, const bool saveIfDefault=false)
- virtual void **saveField** (const std::string &key, Util::TimeUnit value, const Util::TimeUnit defaultValue, const bool saveIfDefault=false)
- **PersistenceRecord** (Persistence_if &config)
- std::size_t **size** () const

  Returns the number of distinct entries in the record.
- void **insert** (Entry entry)

  Inserts a raw entry in the record.
- void insert (Iterator it, Iterator end)

  Inserts multiple entries from the given iterators.
- void **erase** (const std::string &key)

  Removes a specific entry from the record.
- void **clear** ()

  Removes all entries from this record.
- Iterator **find** (const std::string &key)

  Returns an iterator over a specific entry, if found.
- Iterator **begin** ()

  Returns an iterator over raw entries.
- Iterator **end** ()

  Past-the-end sentinel iterator.

17.558.1 Detailed Description

Serialization/Deserialization structure which behaves like an associative array.
Simulation models/components/definitions use this as a "visitor", which is guided across their innards during ser/deserialization and filled with fields. See `PersistentObject_base`.
When this structure reaches the main model persistence interface, it finishes the serialization process in a format-specific manner. See `Persistence_if` and `Serializer`.

17.558.2 Member Function Documentation

17.558.2.1 insert()

```
void PersistenceRecord::insert (
            Iterator it,
            Iterator end )
```

Inserts multiple entries from the given iterators.
Insert the raw entry payload from the source iterator range. Skip entries that already exist to avoid overwriting without warning.
The documentation for this class was generated from the following files:

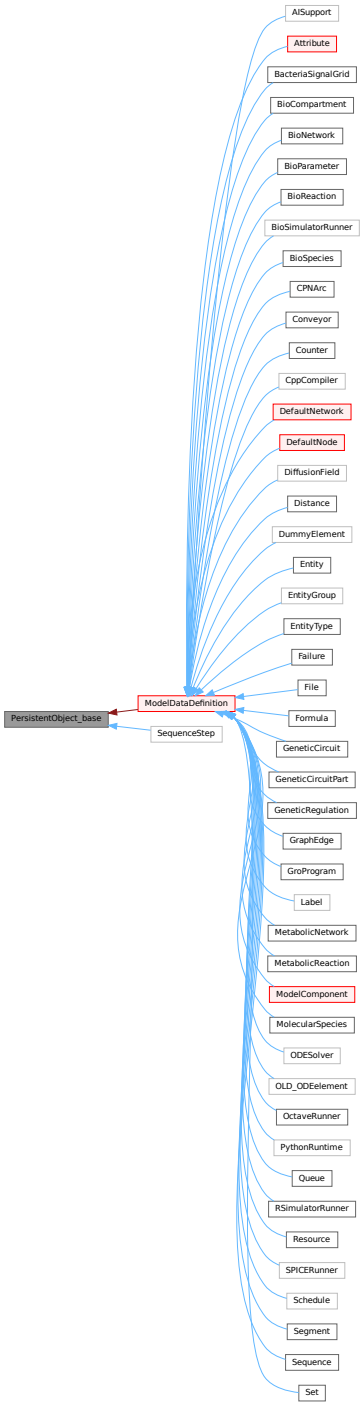
- kernel/simulator/Persistence.h
- kernel/simulator/Persistence.cpp

17.559 PersistentObject_base Class Reference

Dynamic serializable interface.

`#include <kernel/simulator/Persistence.h>`

Inheritance diagram for PersistentObject_base:



Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord ∗fields)=0

  Loads object fields from a deserialization structure.

- virtual void _saveInstance (PersistenceRecord ∗fields, bool saveDefaultValues=false)=0

Saves object fields into a serialization structure.

17.559.1 Detailed Description

Dynamic serializable interface.
Any object that's supposed to be saved to and/or loaded from a file must implement this interface.

17.559.2 Member Function Documentation

17.559.2.1 _loadInstance()

```
virtual bool PersistentObject_base::_loadInstance (
            PersistenceRecord * fields )  [protected], [pure virtual]
```

Loads object fields from a deserialization structure.

Parameters

fields	a table-like structure which can be queried for parsed fields.

Returns

a boolean which is true iff the load operation was successful.

Implemented in Attribute, Counter, Entity, EntityType, StatisticsCollector, ModelComponent, ModelDataDefinition, SinkModelComponent, SourceModelComponent, AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState, GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent, DiffEquations, DiffusionSimulate, LSODE, OLD_ODEelement, Decide, DropOff, Remove, Search, Buffer, Clone, Delay, Process, Release, Seize, SPICECircuit, Resistor, Vsource, Vpulse, Vsine, Capacitor, Diode, PMOS, NMOS, NOT, NAND, AND, NOR, OR, XOR, XNOR, SPICENode, CppForG, PythonForG, RSimulator, Batch, Separate, Record, Write, Assign, Create, Dispose, Access, Enter, Exit, Leave, Move, PickStation, Route, Start, Stop, Store, Unstore, CellularAutomataComp, DefaultNode, FSMState, ModalModelDefault, PetriPlace, Submodel, Match, Signal, Wait, DummyComponent, BioStateProjectionComponent, CellCycleCheckpointComponent, CellDivisionEvent, CellFateDecisionComponent, CellGrowthComponent, CompartmentExchangeComponent, EukaryoticCellCycleComponent, FtsZPolymerizationComponent, MetabolicStateProjectionComponent, MetabolicSubmodelCompone PathwayStressResponseComponent, ResourceAllocationComponent, StochasticReactionComponent, StochasticTranscription, StochasticTranslation, AISupport, BacteriaSignalGrid, BioNetwork, BioParameter, BioReaction, BioSimulatorRunner, BioSpecies, GeneticCircuit, GeneticCircuitPart, GeneticRegulation, GroProgram, MetabolicNetwork, MetabolicReaction, DiffusionField, ODESolver, Failure, Queue, Resource, Schedule, CppCompiler, OctaveRunner, PythonRuntime, RSimulatorRunner, SPICERunner, EntityGroup, File, Formula, Label, Set, Variable, Conveyor, Distance, Segment, SequenceStep, Sequence, Station, Storage, Transporter, ColoredPetriNetNetwork, CPNArc, CPNTransition, DefaultNetwork, EFSMNetwork, GraphEdge, GraphNetwork, MarkovChainNetwork, SignalData, DummyElement, BioCompartment, MolecularSpecies, StochasticReactionRule, and WholeCellState.

17.559.2.2 _saveInstance()

```
virtual void PersistentObject_base::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues = false )  [protected], [pure virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Implemented in Attribute, Counter, Entity, EntityType, StatisticsCollector, ModelComponent, ModelDataDefinition, SinkModelComponent, SourceModelComponent, AIAssistant, MarkovChain, BacteriaColony, BioRunnerCommand, BioSimulate, BioSteadyState, GeneticCircuitSimulate, GeneticExpressionStep, MetabolicFluxBalance, ContinuousSystemComponent

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model ∗model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ∼**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

Returns the unique identifier of this instance.

- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()

17.560.1 Member Function Documentation

17.560.1.1 _loadInstance()

```
bool PetriPlace::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from DefaultNode.

17.560.1.2 _saveInstance()

```
void PetriPlace::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from DefaultNode.

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

17.562.1 Detailed Description

PickStation module DESCRIPTION The PickStation module allows an entity to select a particular station from the multiple stations specified. This module picks among the group of stations based on the selection logic defined with the module. The entity may then route, transport, convey, or connect to the station specified. If the method chosen is connect, the selected station is assigned to an entity attribute. The station selection process is based on the minimum or maximum value of a variety of system variables and expressions. TYPICAL USES A part sent to a processing station based on machine's availability at each station A loan application sent to a set of loan officers based on the number sent to each officer A customer selecting among cashier lines based on the least number waiting in each line PROMPTS Prompt Description Name Unique name of the module that will be displayed in the flowchart. Test Condition Test condition to use for the station selection process, either Minimum or Maximum. Number En Route to Station The number of entities transferring to the station is considered in the station selection process. Number in Queue The number of entities in the queue at the station is considered in the station selection process. Number of Resources Busy The number of busy resources at the station is considered in the station selection process. Expression Determines if an additional user-defined expression is considered in the station selection process. Transfer Type Determines how an entity will be transferred out of this module to its next destination station—either Route, Convey, Transport, or Connect. Save Attribute Defines the name of the attribute that will store the station name that is selected, visible when the transfer method is Connect. Route Time Move time of the entity from its current station to the station determined through this module. Units Time units for route-time parameters.

17.562.2 Member Function Documentation

17.562.2.1 _addSimulationControl()

```
void PickStation::_addSimulationControl (
            SimulationControl * property )  [override], [protected], [virtual]
```

This method is necessary only for those components that instantiate internal elements that must exist before simulation starts and even before model checking. That's the case of components that have internal StatisticsCollectors, since others components may refer to them as expressions (as in "TVAG(ThisCSTAT)") and therefore the modeldatum must exist before checking such expression
Reimplemented from ModelDataDefinition.

17.562.2.2 _check()

```
bool PickStation::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.562.2.3 _createEditableDataDefinitions()

```
void PickStation::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.562.2.4 _getParserChangesInformation()

```
ParserChangesInformation * PickStation::_getParserChangesInformation ( )  [override], [protected],
[virtual]
```

This method returns all changes in the parser that are needed by plugins of this ModelDatas. When connecting a new plugin, ParserChangesInformation are used to change parser source code, whch is after compiled and dinamically linked to to simulator kernel to reflect the changes
Reimplemented from ModelDataDefinition.

17.562.2.5 _initBetweenReplications()

```
void PickStation::_initBetweenReplications ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.562.2.6 _loadInstance()

```
bool PickStation::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.562.2.7 _onDispatchEvent()

```
void PickStation::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.562.2.8 _saveInstance()

```
void PickStation::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.562.2.9 show()

```
std::string PickStation::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

- plugins/components/MaterialHandling/PickStation.h
- plugins/components/MaterialHandling/PickStation.cpp

17.563 PickUp Class Reference

Removes a consecutive run of entities from a queue, appending them to the incoming entity's group.
`#include <plugins/components/Decisions/PickUp.h>`

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

Returns the user-visible label of this instance.

- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.

- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.

- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.

- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.

- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.

- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.

- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.

- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.

- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.

- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.

- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.

- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.

- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Additional Inherited Members

Public Types inherited from Remove

- enum class **RemoveFromType** : int { **QUEUE** = 0 , **ENTITYGROUP** = 1 , **num_elements** = 2 }

Protected Member Functions inherited from Remove

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes
- virtual void _createEditableDataDefinitions () override

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual ParserChangesInformation * _getParserChangesInformation ()
- virtual void _initBetweenReplications ()

- TraceManager::Level **_traceLevelSpecific**
- bool **_traceLevelSpecificEnabled** = false

17.563.1 Detailed Description

Removes a consecutive run of entities from a queue, appending them to the incoming entity's group.
Arena correspondence: the "Pickup module" (Rockwell Automation, *Getting Started with Arena*, "The Advanced Process Panel", p. 57). Implemented by inheriting from Remove and reusing its Queue Name/Starting Rank plumbing (a start/end rank range plays the role of Arena's Quantity).
The documentation for this class was generated from the following files:

- plugins/components/Decisions/PickUp.h
- plugins/components/Decisions/PickUp.cpp

17.564 genesys::launcher::PlatformInfo Struct Reference

Static Public Member Functions

- static PlatformInfo **detect** (const QString &osReleasePath=QStringLiteral("/etc/os-release"), const QString &architectureOverride={})

Public Attributes

- QString **osId**
- QString **osVersion**
- QString **architecture**
- QString **manifestKey**
- bool **valid** = false

The documentation for this struct was generated from the following files:

- applications/launcher/PlatformInfo.h
- applications/launcher/PlatformInfo.cpp

17.565 Plugin Class Reference

`#include <kernel/simulator/Plugin.h>`

Public Member Functions

- Plugin (std::string filename_so_dll)

  Creates a plugin wrapper for a dynamic library file.
- Plugin (StaticGetPluginInformation getInformation)

  Creates a plugin wrapper from a compiled-in metadata callback.
- virtual ~**Plugin** ()

  Releases metadata allocated for the wrapped plugin.
- std::string show ()

  Returns a human-readable description of the plugin state.
- bool isIsValidPlugin () const

  Indicates whether the plugin metadata was successfully initialized.
- PluginInformation * getPluginInfo () const

  Returns the plugin metadata object.
- ModelDataDefinition * loadNew (Model *model, PersistenceRecord *fields)

  Creates a new data definition instance from serialized fields.
- bool loadAndInsertNew (Model *model, PersistenceRecord *fields)

  Loads a new instance and inserts it into the model in one step.
- ModelDataDefinition * newInstance (Model *model, std::string name="")

  Creates a new in-memory instance of the plugin's primary type.

17.565.1 Detailed Description

A Plugin represents a dynamically linked component class (ModelComponent) or modeldatum class (ModelDataDefinition); It gives access to a ModelComponent so it can be used by the model. Classes like Create, Delay, and Dispose are examples of PlugIns. It corresponds directly to the "Expansible" part (the capitalized 'E') of the GenESyS acronymous PlugIns are NOT implemented yet

17.565.2 Constructor & Destructor Documentation

17.565.2.1 Plugin() [1/2]

```
Plugin::Plugin (
            std::string filename_so_dll )
```

Creates a plugin wrapper for a dynamic library file.

Parameters

filename_so_dll	Plugin library filename or path.

17.565.2.2 Plugin() [2/2]

```
Plugin::Plugin (
            StaticGetPluginInformation getInformation )
```

Creates a plugin wrapper from a compiled-in metadata callback.

Parameters

getInformation	Callback that returns the plugin metadata.

17.565.3 Member Function Documentation

17.565.3.1 getPluginInfo()

```
PluginInformation * Plugin::getPluginInfo ( ) const
```

Returns the plugin metadata object.

Returns

Plugin information block, or `nullptr` when invalid.

17.565.3.2 isIsValidPlugin()

```
bool Plugin::isIsValidPlugin ( ) const
```

Indicates whether the plugin metadata was successfully initialized.

Returns

`true` when this wrapper contains a valid plugin.

17.565.3.3 loadAndInsertNew()

```
bool Plugin::loadAndInsertNew (
            Model * model,
            PersistenceRecord * fields )
```

Loads a new instance and inserts it into the model in one step.

Parameters

model	Parent model that will own the new instance.
fields	Serialized fields to deserialize.

Returns

`true` when loading and insertion succeed.

17.565.3.4 loadNew()

```
ModelDataDefinition * Plugin::loadNew (
            Model * model,
            PersistenceRecord * fields )
```

Creates a new data definition instance from serialized fields.

Creates a new ModelDataDefinition from fields loaded from a file or another persistence source.

Parameters

model	Parent model that will own the new instance.
fields	Serialized fields to deserialize.

Returns

New data definition instance, or `nullptr` on failure.

17.565.3.5 newInstance()

```
ModelDataDefinition * Plugin::newInstance (
            Model * model,
            std::string name = "" )
```

Creates a new in-memory instance of the plugin's primary type.

Parameters

model	Parent model that will own the instance.
name	Initial object name.

Returns

Newly created instance, or `nullptr` on failure.

17.565.3.6 show()

`std::string Plugin::show ( )`
Returns a human-readable description of the plugin state.

Returns

Textual summary used in traces and diagnostics.

responsibilities should remain in PluginConnector/PluginManager layers.
The documentation for this class was generated from the following files:

- kernel/simulator/Plugin.h
- kernel/simulator/Plugin.cpp

17.566 PluginCatalogController Class Reference

Controller responsible for plugin catalog presentation and plugin palette behavior.
`#include <applications/gui/genesys/controllers/PluginCatalogController.h>`

Public Member Functions

- **PluginCatalogController** (Simulator *simulator, QTreeWidget *pluginsTree, QPlainTextEdit *modelText↩ Editor, std::map< std::string, QColor > *pluginCategoryColor)

  Creates the plugin-catalog controller used by MainWindow compatibility slots.
- void **insertPluginUI** (Plugin *plugin) const

  Inserts one plugin entry into the categorized plugin tree representation.
- void **reloadFromPluginManager** () const

  Rebuilds the categorized plugin tree from the current PluginManager state.
- void **applyCategoryExpansionPolicy** () const

  Applies the default expansion policy for plugin category roots.
- void **showContextMenu** (const QPoint &pos) const

  Shows the plugin-tree context menu used to reorder top-level categories.
- void **insertFakePlugins** () const

  Inserts compatibility fake plugins used by legacy GUI flows.
- void **handlePluginItemDoubleClicked** (QTreeWidgetItem *item, int column) const

  Handles plugin double-click by delegating insertion/selection behavior.
- void **handlePluginItemClicked** (QTreeWidgetItem *item, int column) const

  Handles plugin single-click behavior without mutating model lifecycle state.
- void **moveTopLevelCategory** (QTreeWidgetItem *item, int delta) const

  Moves a top-level category before or after its siblings.

17.566.1 Detailed Description

Controller responsible for plugin catalog presentation and plugin palette behavior.
This controller encapsulates the plugin-tree behavior used by MainWindow wrappers, keeping plugin browsing and insertion affordances consistent while reducing direct widget logic in the MainWindow compatibility façade.
Responsibilities:

- populate plugin entries grouped by category with legacy color conventions;
- provide compatibility helpers for fake-plugin insertion paths;
- react to plugin-tree click/double-click events delegated by MainWindow.

Boundaries:

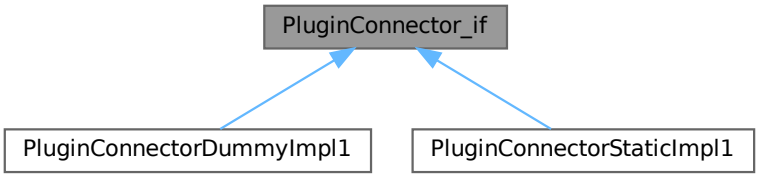
- it does not load plugin binaries or manage kernel plugin lifecycle;
- it does not own textual model synchronization beyond delegated editor insertions;
- it is a UI controller layer, not a persistence/export service.

The documentation for this class was generated from the following files:

- applications/gui/genesys/controllers/PluginCatalogController.h
- applications/gui/genesys/controllers/PluginCatalogController.cpp

17.567 PluginConnector_if Class Reference

Interface for dynamic discovery/loading/unloading of plugin libraries.
`#include <kernel/simulator/PluginConnector_if.h>`
Inheritance diagram for PluginConnector_if:



Public Member Functions

- virtual Plugin * check (const std::string dynamicLibraryFilename)=0
  check
- virtual Plugin * connect (const std::string dynamicLibraryFilename)=0
  connect
- virtual List< std::string > * find ()=0
  find dynamicLibraryFilenames
- virtual bool disconnect (const std::string dynamicLibraryFilename)=0
  disconnect
- virtual bool disconnect (Plugin *plugin)=0
  disconnect

17.567.1 Detailed Description

Interface for dynamic discovery/loading/unloading of plugin libraries.
Connector implementations bridge OS-level dynamic library handling and the kernel plugin abstraction, validating candidates and managing plugin lifecycles.

17.567.2 Member Function Documentation

17.567.2.1 check()

```
virtual Plugin * PluginConnector_if::check (
            const std::string dynamicLibraryFilename )  [pure virtual]
```

check

Parameters

dynamicLibraryFilename	

Returns

Validates whether a dynamic library contains a compatible plugin without permanently connecting it.
Implemented in PluginConnectorDummyImpl1, and PluginConnectorStaticImpl1.

17.567.2.2 connect()

```
virtual Plugin * PluginConnector_if::connect (
            const std::string dynamicLibraryFilename )  [pure virtual]
```

connect

Parameters

dynamicLibraryFilename	

Returns

Loads and connects a plugin from a dynamic library.
Implemented in PluginConnectorDummyImpl1, and PluginConnectorStaticImpl1.

17.567.2.3 disconnect() [1/2]

```
virtual bool PluginConnector_if::disconnect (
            const std::string dynamicLibraryFilename )  [pure virtual]
```

disconnect

Parameters

dynamicLibraryFilename	

Returns

List of all Plugins found and connected

Disconnects the plugin associated with the provided library file.
Implemented in PluginConnectorDummyImpl1, and PluginConnectorStaticImpl1.

17.567.2.4 disconnect() [2/2]

```
virtual bool PluginConnector_if::disconnect (
            Plugin * plugin )  [pure virtual]
```

disconnect

Parameters

plugin	

Returns

Disconnects a previously connected plugin instance.
Implemented in PluginConnectorDummyImpl1, and PluginConnectorStaticImpl1.

17.567.2.5 find()

```
virtual List< std::string > * PluginConnector_if::find ( )  [pure virtual]
```

find dynamicLibraryFilenames

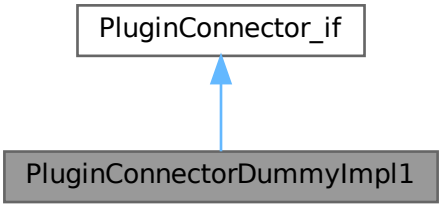
Parameters

return List of dynamicLibraryFilenames
Searches for candidate plugin libraries in the configured environment.
Implemented in PluginConnectorDummyImpl1, and PluginConnectorStaticImpl1.
The documentation for this class was generated from the following file:

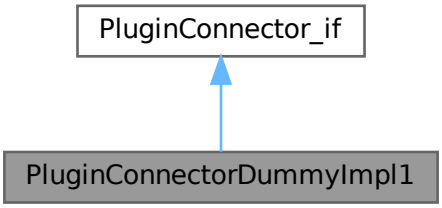
- kernel/simulator/PluginConnector_if.h

17.568 PluginConnectorDummyImpl1 Class Reference

In-memory plugin connector that resolves built-in plugin metadata.
`#include <plugins/PluginConnectorDummyImpl1.h>`
Inheritance diagram for PluginConnectorDummyImpl1:



Collaboration diagram for PluginConnectorDummyImpl1:



Public Member Functions

- Plugin * check (const std::string dynamicLibraryFilename) override
  Verifies whether a built-in plugin name can be resolved.
- Plugin * connect (const std::string dynamicLibraryFilename) override
  Resolves a built-in plugin by filename alias.
- List< std::string > * find () override
  Returns the list of built-in plugin filenames recognized by this connector.
- bool disconnect (const std::string dynamicLibraryFilename) override
  Disconnects a plugin identified by filename.
- bool disconnect (Plugin *plugin) override
  Disconnects a plugin instance.

17.568.1 Detailed Description

In-memory plugin connector that resolves built-in plugin metadata.
This connector does not load shared libraries. Instead, it maps known file names to compiled-in plugin classes and returns the corresponding metadata.

17.568.2 Member Function Documentation

17.568.2.1 check()

```
Plugin * PluginConnectorDummyImpl1::check (
            const std::string dynamicLibraryFilename )  [override], [virtual]
```

Verifies whether a built-in plugin name can be resolved.

Parameters

dynamicLibraryFilename	Plugin library filename or alias.

Returns

Metadata for the resolved plugin, or `nullptr` if unknown.

Implements PluginConnector_if.

17.568.2.2 connect()

```
Plugin * PluginConnectorDummyImpl1::connect (
            const std::string dynamicLibraryFilename )  [override], [virtual]
```

Resolves a built-in plugin by filename alias.

Parameters

dynamicLibraryFilename	Plugin library filename or alias.

Returns

Metadata for the resolved plugin, or `nullptr` if unknown.

Implements PluginConnector_if.

17.568.2.3 disconnect() [1/2]

```
bool PluginConnectorDummyImpl1::disconnect (
            const std::string dynamicLibraryFilename )  [override], [virtual]
```

Disconnects a plugin identified by filename.

Parameters

dynamicLibraryFilename	Plugin library filename or alias.

Returns

Always `true` in the current dummy implementation.

Implements PluginConnector_if.

17.568.2.4 disconnect() [2/2]

```
bool PluginConnectorDummyImpl1::disconnect (
            Plugin * plugin )  [override], [virtual]
```

Disconnects a plugin instance.

Parameters

plugin	Plugin instance to disconnect.

Returns

Always `true` in the current dummy implementation.

Implements PluginConnector_if.

17.568.2.5 find()

```
List< std::string > * PluginConnectorDummyImpl1::find ( )  [override], [virtual]
```

Returns the list of built-in plugin filenames recognized by this connector.

Returns

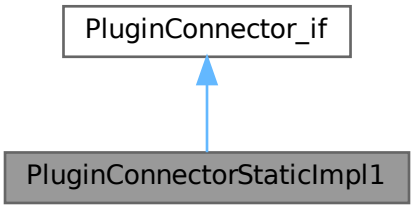
Newly allocated list with known plugin aliases.

Implements PluginConnector_if.
The documentation for this class was generated from the following files:

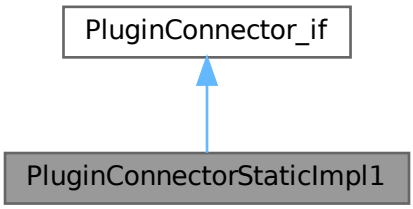
- plugins/PluginConnectorDummyImpl1.h
- kernel/simulator/PluginConnectorDummyBootstrap.cpp
- plugins/PluginConnectorDummyImpl1.cpp

17.569 PluginConnectorStaticImpl1 Class Reference

Static plugin connector stub used by the kernel interface.
`#include <plugins/PluginConnectorStaticImpl1.h>`
Inheritance diagram for PluginConnectorStaticImpl1:



Collaboration diagram for PluginConnectorStaticImpl1:



Public Member Functions

- Plugin * check (const std::string dynamicLibraryFilename) override
  Checks whether a plugin library can be connected.
- Plugin * connect (const std::string dynamicLibraryFilename) override
  Connects a plugin library.
- List< std::string > * find () override
  Lists the available plugin libraries.
- bool disconnect (const std::string dynamicLibraryFilename) override
  Disconnects a plugin by library filename.
- bool disconnect (Plugin *plugin) override
  Disconnects a plugin instance.

17.569.1 Detailed Description

Static plugin connector stub used by the kernel interface.
This implementation currently provides a no-op connector that satisfies the plugin connector contract without loading dynamic libraries.

17.569.2 Member Function Documentation

17.569.2.1 check()

```
Plugin * PluginConnectorStaticImpl1::check (
            const std::string dynamicLibraryFilename )  [override], [virtual]
```

Checks whether a plugin library can be connected.

Parameters

dynamicLibraryFilename	Path to the plugin library.

Returns

Always `nullptr` in the current static stub implementation.

Implements PluginConnector_if.

17.569.2.2 connect()

```
Plugin * PluginConnectorStaticImpl1::connect (
            const std::string dynamicLibraryFilename )  [override], [virtual]
```

Connects a plugin library.

Parameters

dynamicLibraryFilename	Path to the plugin library.

Returns

Always `nullptr` in the current static stub implementation.

Implements PluginConnector_if.

17.569.2.3 disconnect() [1/2]

```
bool PluginConnectorStaticImpl1::disconnect (
            const std::string dynamicLibraryFilename )  [override], [virtual]
```

Disconnects a plugin by library filename.

Parameters

dynamicLibraryFilename	Path to the plugin library.

Returns

Always `true` in the current static stub implementation.

Implements PluginConnector_if.

17.569.2.4 disconnect() [2/2]

```
bool PluginConnectorStaticImpl1::disconnect (
            Plugin * plugin )  [override], [virtual]
```

Disconnects a plugin instance.

Parameters

plugin	Plugin instance to disconnect.

Returns

Always `true` in the current static stub implementation.

Implements PluginConnector_if.

17.569.2.5 find()

`List< std::string > * PluginConnectorStaticImpl1::find ( ) [override], [virtual]`
Lists the available plugin libraries.

Returns

Always `nullptr` in the current static stub implementation.

Implements PluginConnector_if.
The documentation for this class was generated from the following files:

- plugins/PluginConnectorStaticImpl1.h
- plugins/PluginConnectorStaticImpl1.cpp

17.570 PluginInformation Class Reference

Static Public Member Functions

- static std::string **categoryFolderName** (const std::string &category)

The documentation for this class was generated from the following files:

- kernel/simulator/PluginInformation.h
- kernel/simulator/PluginInformation.cpp

17.571 PluginInsertionOptions Struct Reference

Optional policy hooks used while inserting a plugin.
`#include <kernel/simulator/PluginManager.h>`

Public Attributes

- std::function< bool(const SystemDependencyCheckResult &)> **confirmSystemDependencyInstallation**

  Called before running any install command for missing system dependencies.

17.571.1 Detailed Description

Optional policy hooks used while inserting a plugin.
The kernel reports dependency diagnostics through this structure and leaves user confirmation to the caller. An empty callback means non-interactive insertion: missing dependencies are reported through traces and no install command is executed.
The documentation for this struct was generated from the following file:

- kernel/simulator/PluginManager.h

17.572 PluginLoadIssue Class Reference

Diagnostic record for a plugin candidate that could not be loaded.
`#include <kernel/simulator/PluginManager.h>`

Public Types

- enum class Reason {
  InvalidPlugin , **MissingSystemDependency** , **DynamicDependencyFailure** , **ConnectionFailure** , **InsertionFailure** , **Exception** }

  High-level reason why a plugin candidate was not loaded.

Public Member Functions

- **PluginLoadIssue** ()

  Creates an empty diagnostic record.
- **PluginLoadIssue** (std::string filename, std::string pluginTypename, Reason reason, std::string message, SystemDependencyCheckResult systemDependencyResult={}) noexcept

  Creates a diagnostic record for a failed plugin load attempt.
- const std::string & **getFilename** () const

  Returns the filename passed to the plugin connector.
- const std::string & **getPluginTypename** () const

  Returns the plugin typename when it could be read from PluginInformation.
- Reason **getReason** () const

  Returns the high-level failure reason.
- const std::string & **getMessage** () const

  Returns the human-readable diagnostic message captured by the manager.
- const SystemDependencyCheckResult & **getSystemDependencyResult** () const

  Returns dependency diagnostics captured during system dependency preflight.
- bool **hasSystemDependencyResult** () const

  Returns true when this issue includes system dependency diagnostics.
- std::string **diagnosticText** () const

  Formats the issue for trace logs or GUI details.

Static Public Member Functions

- static std::string **reasonToString** (Reason reason)

  Returns a stable textual label for a failure reason.

17.572.1 Detailed Description

Diagnostic record for a plugin candidate that could not be loaded.
The manager keeps these records so interactive front-ends can explain startup autoload failures after the application UI is ready. The kernel stores only technical diagnostics; GUI code decides how to present and resolve them.
The documentation for this class was generated from the following files:

- kernel/simulator/PluginManager.h
- kernel/simulator/PluginManager.cpp

17.573 PluginManager Class Reference

Manages discovery, loading, lookup and instantiation of simulation plugins.
`#include <kernel/simulator/PluginManager.h>`

Public Member Functions

- **PluginManager** (Simulator *simulator)

  Creates a plugin manager bound to a simulator instance.
- PluginManager (Simulator *simulator, PluginConnector_if *pluginConnector, SystemCommandExecutor_if *systemCommandExecutor)

  Creates a plugin manager with injectable connector and command executor.
- virtual ~**PluginManager** ()

  Destroys owned plugin wrappers and connector resources.
- std::string **show** ()

  Returns a human-readable summary of currently connected plugins.
- List< Plugin * > * **completePluginsFieldsAndTemplates** ()

Completes plugin metadata (fields/templates) after loading.

- bool **check** (const std::string &dynamicLibraryFilename)

  Validates whether a dynamic library provides a compatible plugin.
- SystemDependencyCheckResult **checkSystemDependencies** (const std::string &dynamicLibraryFilename)

  Evaluates system dependencies declared by a dynamic-library plugin without inserting it.
- List< std::string > * **discoverPluginFilenames** () const

  Discovers plugin filenames through the configured connector without inserting them.
- List< PluginLoadIssue > * **getPluginLoadIssues** () const

  Returns plugin candidates that failed to load during check/connect/preflight.
- void **clearPluginLoadIssues** ()

  Clears all stored plugin load diagnostics.
- void **clearPluginLoadIssue** (const std::string &dynamicLibraryFilename)

  Removes stored diagnostics for one plugin candidate filename.
- Plugin * **insert** (const std::string &dynamicLibraryFilename)

  Loads and inserts a plugin from a dynamic library file.
- Plugin * **insert** (const std::string &dynamicLibraryFilename, const PluginInsertionOptions &options)

  Loads and inserts a plugin, optionally asking the caller to authorize dependency installation.
- bool **remove** (const std::string &dynamicLibraryFilename)

  Removes/disconnects a plugin by its dynamic library filename.
- bool **remove** (Plugin *plugin)

  Removes/disconnects a plugin by pointer.
- Plugin * **find** (const std::string &pluginTypeName)

  Finds a connected plugin by plugin type name.
- std::vector< std::string > getDataDefinitionPluginTypenames () const

  Returns connected plugin type names that can create ModelDataDefinition instances.
- std::string **sourceIncludePathFor** (const std::string &pluginTypeName)

  Returns the source include path for a connected plugin type.
- List< Plugin * > * **autoInsertPlugins** (const std::string &pluginsListFilename, const bool lookForPluginsIf↩ FilenameNotFound=true)

  Auto-loads plugins listed in file (or discovered automatically as fallback).
- List< Plugin * > * **autoInsertPlugins** (const std::string &pluginsListFilename, const bool lookForPluginsIf↩ FilenameNotFound, const PluginInsertionOptions &options)

  Auto-loads plugins listed in file using insertion policy hooks.
- List< Plugin * > * **autoInsertPlugins** ()

  Auto-loads plugins discovered automatically).
- List< Plugin * > * **autoInsertPlugins** (const PluginInsertionOptions &options)

  Auto-loads plugins discovered automatically using insertion policy hooks.
- Plugin * **front** ()

  Returns the first plugin in the internal plugin list.
- Plugin * **next** ()

  Returns the next plugin using the internal iterator cursor.
- Plugin * **last** ()

  Returns the last plugin in the internal plugin list.
- unsigned int **size** ()

  Returns the number of connected plugins.
- Plugin * **getAtRank** (unsigned int rank)

  Returns the plugin at a specific list rank.
- ModelDataDefinition * **newInstance** (const std::string &pluginTypename, Model *model, std::string name="")

  Creates a new model data/component instance using a plugin typename.
- template<typename T >
  T * **newInstance** (Model *model, std::string name="")

17.573.1 Detailed Description

Manages discovery, loading, lookup and instantiation of simulation plugins.
The plugin manager centralizes dynamic-library checks/connections through a `PluginConnector_if` and keeps the in-memory list of connected plugins used by the simulator to create model data/component instances.

17.573.2 Constructor & Destructor Documentation

17.573.2.1 PluginManager()

```
PluginManager::PluginManager (
            Simulator * simulator,
            PluginConnector_if * pluginConnector,
            SystemCommandExecutor_if * systemCommandExecutor )
```

Creates a plugin manager with injectable connector and command executor.
Ownership of both injected pointers is transferred to the manager. This constructor exists primarily for unit tests and narrow integration seams.

17.573.3 Member Function Documentation

17.573.3.1 getDataDefinitionPluginTypenames()

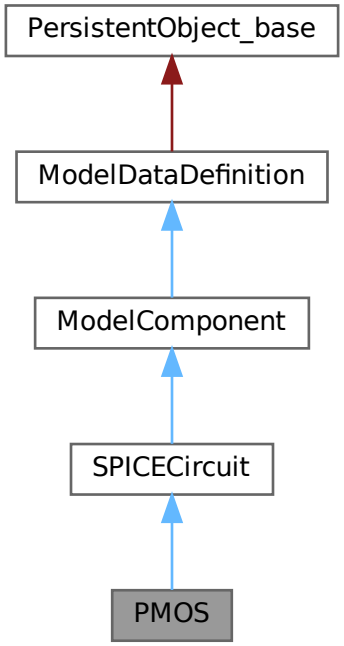
```
std::vector< std::string > PluginManager::getDataDefinitionPluginTypenames ( ) const
```

Returns connected plugin type names that can create ModelDataDefinition instances.
Polymorphic data structures such as Set use this snapshot to expose concrete, creatable element types to editors without hard-coding plugin names in the GUI.
The documentation for this class was generated from the following files:

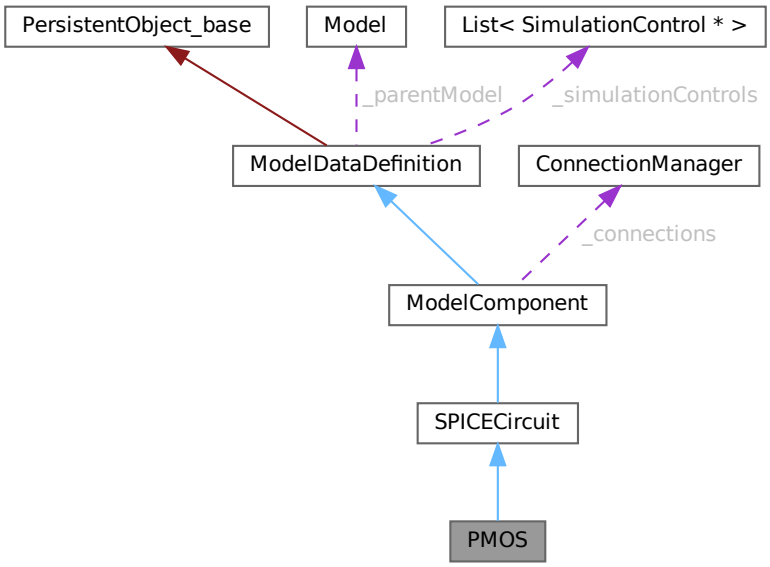
- kernel/simulator/PluginManager.h
- kernel/simulator/PluginManager.cpp

17.574 PMOS Class Reference

Inheritance diagram for PMOS:



Collaboration diagram for PMOS:



Public Member Functions

- **PMOS** (Model *model, std::string name="")
- void Build () override
- void **setWidth** (float width)
- void **setLength** (float length)
- void **setElectricalModel** (std::string electricalModel)

Public Member Functions inherited from SPICECircuit

- **SPICECircuit** (Model *model, std::string name="")

  constructors
- void **setRunner** (SPICERunner *runner)

  new public user methods for this components
- SPICERunner * **getRunner** ()
- virtual std::string show () override

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

Returns the user-visible label of this instance.

- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.

- Model * getParentModel () const

  Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.

- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.

- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.

- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.

- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.

- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.

- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.

- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.

- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.

- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.

- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.

- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.

- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.

- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from SPICECircuit

- static PluginInformation * **GetPluginInformation** ()

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component

- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")
- static std::vector< std::string > **split** (std::string word, char split_char)

  Externalize function GetPluginInformation to be accessible throught dynamic linked library.

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.

Protected Member Functions inherited from SPICECircuit

- void **BuildCircuit** (std::string description, unsigned int id, std::vector< std::string > the_params={""}, std::string the_model="", std::string the_model_file="")

  virtual protected method that must be overriden
- void **UpdateConnections** ()
- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  This method is only for ModelComponents, not ModelDataElements.
- virtual void _createNonEditableDataDefinitions () override

  virtual protected methods that could be overriden by derived classes, if needed

Protected Member Functions inherited from ModelDataDefinition

- bool _getSaveDefaultsOption ()
- virtual bool _check (std::string &errorMessage)

  could be overriden by derived classes
- virtual ParserChangesInformation * _getParserChangesInformation ()
- virtual void _initBetweenReplications ()
- virtual void _addSimulationControl (SimulationControl *control)
- virtual void _createInternalAndAttachedData ()
- virtual void **_createInternalStatisticReporters** ()
- virtual void _createAttachedAttributes ()
- virtual void _createEditableDataDefinitions ()
- void **_templateCreateInternalStatisticReporters** ()
- void **_templateCreateAttachedAttributes** ()
- void **_templateCreateNonEditableDataDefinitions** ()
- void **_templateCreateEditableDataDefinitions** ()
- void **_internaStatisticReportersClear** ()

  legacy helper methods used by the granular create hooks*
- void **_internalDataClear** ()
- void **_internalDataInsert** (const std::string &key, ModelDataDefinition *child)
- void **_internalDataRemove** (const std::string &key)
- void **_attachedDataClear** ()
- void **_attachedDataInsert** (const std::string &key, ModelDataDefinition *data)
- void **_attachedDataRemove** (const std::string &key)
- void **_attachedAttributesInsert** (const std::vector< std::string > &neededNames)
- void **_statisticReporterInsert** (const std::string &key, ModelDataDefinition *data)
- void **_statisticReporterRemove** (const std::string &key)
- void **_statisticReportersClear** ()
- void **_mandatoryAttachedAttributeInsert** (const std::string &key, ModelDataDefinition *data)
- void **_mandatoryAttachedAttributeRemove** (const std::string &key)
- void **_mandatoryAttachedAttributesClear** ()
- void **_mandatoryEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_mandatoryEditableDataDefinitionRemove** (const std::string &key)
- void **_mandatoryEditableDataDefinitionsClear** ()
- void **_optionalEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_optionalEditableDataDefinitionRemove** (const std::string &key)
- void **_optionalEditableDataDefinitionsClear** ()
- void **_mandatoryNonEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_mandatoryNonEditableDataDefinitionRemove** (const std::string &key)
- void **_mandatoryNonEditableDataDefinitionsClear** ()
- void **_optionalNonEditableDataDefinitionInsert** (const std::string &key, ModelDataDefinition *data)
- void **_optionalNonEditableDataDefinitionRemove** (const std::string &key)
- void **_optionalNonEditableDataDefinitionsClear** ()
- void **_checkCreateAttachedReferencedDataDefinition** (const std::string &expression)

  method to be called to insert attached dataelements that are referenced by string expressions (detected by the parser), to avoid orphaned data definitions
- void **trace** (const std::string &text, TraceManager::Level level=TraceManager::Level::L8_detailed)

  not just an easy access to trace manager, but wrappers to check if specific trace level applies
- void **traceError** (const std::string &text, const std::exception &e)
- void **traceError** (const std::string &text, TraceManager::Level level=TraceManager::Level::L1_errorFatal)
- void **traceReport** (const std::string &text, TraceManager::Level level=TraceManager::Level::L2_results)
- void **traceSimulation** (void *thisobject, double time, Entity *entity, ModelComponent *component, const std::string &text, TraceManager::Level level=TraceManager::Level::L8_detailed)
- void traceSimulation (void *thisobject, const std::string &text, TraceManager::Level level=TraceManager::↩ Level::L8_detailed)

  Traces text to the simulation output.
- void **traceSimulation** (void *thisobject, TraceManager::Level level, const std::string &text)

17.574.1 Member Function Documentation

17.574.1.1 _loadInstance()

```
bool PMOS::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from SPICECircuit.

17.574.1.2 _saveInstance()

```
void PMOS::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from SPICECircuit.

17.574.1.3 Build()

```
void PMOS::Build ( )  [override], [virtual]
```

Reimplemented from SPICECircuit.
The documentation for this class was generated from the following files:

- plugins/components/ElectronicsSimulation/SPICECircuit.h
- plugins/components/ElectronicsSimulation/SPICECircuit.cpp

17.577 yy::position Class Reference

A point in a source file.
`#include <parser/location.hh>`

Public Types

- typedef const std::string **filename_type**

  Type for file name.
- typedef int **counter_type**

  Type for line and column numbers.

Public Member Functions

- **position** (filename_type *f=YY_NULLPTR, counter_type l=1, counter_type c=1)

  Construct a position.
- void **initialize** (filename_type *fn=YY_NULLPTR, counter_type l=1, counter_type c=1)

  Initialization.

Line and Column related manipulators

- void **lines** (counter_type count=1)

  (line related) Advance to the COUNT next lines.
- void **columns** (counter_type count=1)

  (column related) Advance to the COUNT next columns.

Public Attributes

- filename_type * **filename**

  File name to which this position refers.
- counter_type **line**

  Current line number.
- counter_type **column**

  Current column number.

Additional Inherited Members

Static Protected Member Functions inherited from ProbabilityDistributionBase

- static double _gammaFunction (double x)
- static double _betaFunction (double x, double y)
- static double _factorial (double x)

17.579.1 Detailed Description

Static façade for inverse/CDF-related distribution utilities.
Architectural role:

- Exposes quantile/inverse computations used by hypothesis testing and confidence-interval routines.

Implementation notes:

- Uses numerical procedures and internal cache state.
- Current static design is legacy-oriented and not the final target model.

Planned evolution:

- Future versions may delegate responsibilities to Distribution_if, Quadrature_if and RootFinder_if abstractions.

17.579.2 Member Function Documentation

17.579.2.1 inverseChi2()

```
double ProbabilityDistribution::inverseChi2 (
            double cumulativeProbability,
            double degreeFreedom )  [static]
```

@TODO: Is there a way to better determine the upper limit?

17.579.2.2 inverseFFisherSnedecor()

```
double ProbabilityDistribution::inverseFFisherSnedecor (
            double cumulativeProbability,
            double d1,
            double d2 )  [static]
```

@TODO: Is there a way to better determine the upper limit?

17.579.2.3 inverseNormal()

```
double ProbabilityDistribution::inverseNormal (
            double cumulativeProbability,
            double mean,
            double stddev )  [static]
```

@TODO: Could be better (separate into 1,2,3xstddev)

17.579.2.4 inverseTStudent()

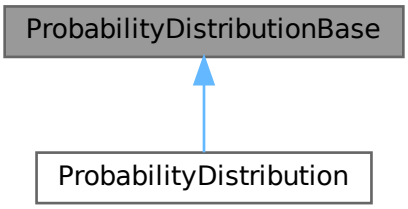
```
double ProbabilityDistribution::inverseTStudent (
            double cumulativeProbability,
            double mean,
            double stddev,
            double degreeFreedom )  [static]
```

@TODO: Could be better
The documentation for this class was generated from the following files:

- tools/Statistics/ProbabilityDistribution.h
- tools/Statistics/ProbabilityDistribution.cpp

17.580 ProbabilityDistributionBase Class Reference

Mathematical base library for distribution-related functions.
`#include <tools/Statistics/ProbabilityDistributionBase.h>`
Inheritance diagram for ProbabilityDistributionBase:



Static Public Member Functions

- static double beta (double x, double alpha, double beta)
- static double chi2 (double x, double degreeFreedom)
- static double erlang (double x, double shape, double scale)
- static double exponential (double x, double mean)
- static double fisherSnedecor (double x, double d1, double d2)
- static double gamma (double x, double shape, double scale)
- static double logNormal (double x, double mean, double stddev)
- static double normal (double x, double mean, double stddev)
- static double poisson (double x, double mean)
- static double triangular (double x, double min, double mode, double max)
- static double tStudent (double x, double mean, double stddev, double degreeFreedom)
- static double uniform (double x, double min, double max)
- static double weibull (double x, double shape, double scale)

Static Protected Member Functions

- static double _gammaFunction (double x)
- static double _betaFunction (double x, double y)
- static double _factorial (double x)

17.580.1 Detailed Description

Mathematical base library for distribution-related functions.
Architectural role:

- Provides static PDF/PMF and helper formulas used by higher-level tools.
- Not an OO hierarchy of distribution objects yet.

Mathematical meaning:

- Public methods represent density/mass functions or mathematically-related helpers for known distributions.

17.580.2 Member Function Documentation

17.580.2.1 _betaFunction()

```
double ProbabilityDistributionBase::_betaFunction (
            double x,
            double y )  [static], [protected]
```

Beta special function helper.

17.580.2.2 _factorial()

```
double ProbabilityDistributionBase::_factorial (
            double x )  [static], [protected]
```

Factorial helper, typically used by PMFs.

17.580.2.3 _gammaFunction()

```
double ProbabilityDistributionBase::_gammaFunction (
            double x )  [static], [protected]
```

Gamma special function approximation/helper. @TODO: Implement by myself

17.580.2.4 beta()

```
double ProbabilityDistributionBase::beta (
            double x,
            double alpha,
            double beta )  [static]
```

Beta distribution PDF.

17.580.2.5 chi2()

```
double ProbabilityDistributionBase::chi2 (
            double x,
            double degreeFreedom )  [static]
```

Chi-square distribution PDF.

17.580.2.6 erlang()

```
double ProbabilityDistributionBase::erlang (
            double x,
            double shape,
            double scale )  [static]
```

Erlang distribution PDF.

17.580.2.7 exponential()

```
double ProbabilityDistributionBase::exponential (
            double x,
            double mean )  [static]
```

Exponential distribution PDF.

17.580.2.8 fisherSnedecor()

```
double ProbabilityDistributionBase::fisherSnedecor (
            double x,
            double d1,
            double d2 )  [static]
```

Fisher-Snedecor F distribution PDF.

17.580.2.9 gamma()

```
double ProbabilityDistributionBase::gamma (
            double x,
            double shape,
            double scale )  [static]
```

Gamma distribution PDF.

17.580.2.10 logNormal()

```
double ProbabilityDistributionBase::logNormal (
            double x,
            double mean,
            double stddev )  [static]
```

Log-normal distribution PDF.

17.580.2.11 normal()

```
double ProbabilityDistributionBase::normal (
            double x,
            double mean,
            double stddev )  [static]
```

Normal distribution PDF.

17.580.2.12 poisson()

```
double ProbabilityDistributionBase::poisson (
            double x,
            double mean )  [static]
```

Poisson distribution PMF.

17.580.2.13 triangular()

```
double ProbabilityDistributionBase::triangular (
            double x,
            double min,
            double mode,
            double max )  [static]
```

Triangular distribution PDF.

17.580.2.14 tStudent()

```
double ProbabilityDistributionBase::tStudent (
            double x,
            double mean,
```

```
            double stddev,
            double degreeFreedom )  [static]
```

Student t distribution PDF.

17.580.2.15 uniform()

```
double ProbabilityDistributionBase::uniform (
            double x,
            double min,
            double max )  [static]
```

Uniform distribution PDF.

17.580.2.16 weibull()

```
double ProbabilityDistributionBase::weibull (
            double x,
            double shape,
            double scale )  [static]
```

Weibull distribution PDF.

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

Returns the parent model that owns this definition.

- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes
- virtual void _createNonEditableDataDefinitions () override
- virtual void _createEditableDataDefinitions () override

Protected Member Functions inherited from ModelDataDefinition

17.582.1 Detailed Description

Composite component that always chains an internal Seize, Delay and Release to model "seize a resource, hold it for a while, release it".
Arena correspondence: the "Process module" (Rockwell Automation, *Getting Started with Arena*, "The Basic Process Panel", pp. 33-35, plus the "Process module — Resource dialog box", p. 35). Priority, the QueueableItem and the SeizeRequests list are forwarded to the internal Seize; the delay expression/time unit are forwarded to the internal Delay; see Seize, Delay and Release for their own accessors.
Known differences from Arena, see `docs/ai_assistants/reference/ARENA_GENESYS_COMPATIBILITY.md` §6.5 for full detail:

- there is no Action selector (Delay / Seize Delay Release / Seize Delay / Delay Release); a Process instance always builds all three sub-components — a standalone Delay is the closest substitute for Arena's resource-free Action variants;
- `setAllocationType()/getAllocationType()` control the internal Seize's allocation category, not the internal Delay's, so a Process component's own processing time stays permanently categorized as "Wait" (Delay's own default) rather than reaching Arena's typical "Value Added" default — flagged as a bug candidate pending maintainer confirmation, not fixed here.

17.582.2 Member Function Documentation

17.582.2.1 _check()

```
bool Process::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.582.2.2 _createEditableDataDefinitions()

```
void Process::_createEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.582.2.3 _createNonEditableDataDefinitions()

```
void Process::_createNonEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.582.2.4 _loadInstance()

```
bool Process::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.582.2.5 _onDispatchEvent()

```
void Process::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.582.2.6 _saveInstance()

```
void Process::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.582.2.7 show()

```
std::string Process::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.

17.590 PropertyEditorController Class Reference

Controller that orchestrates property editor state and scene-selection coupling.
`#include <applications/gui/genesys/controllers/PropertyEditorController.h>`

Public Member Functions

- **PropertyEditorController** (ObjectPropertyBrowser *propertyBrowser, ModelGraphicsView *graphicsView, PropertyEditorGenesys *propertyGenesys, std::map< SimulationControl *, DataComponentProperty * > *propertyList, std::map< SimulationControl *, DataComponentEditor * > *propertyEditorUI, std::map< SimulationControl *, ComboBoxEnum * > *propertyBox, std::function< void()> actualizeModelSim↩ Language, std::function< void(bool)> actualizeModelComponents, std::function< void(bool)> actualize↩ ModelDataDefinitions, std::function< void()> actualizeModelCppCode, std::function< bool()> create↩ ModelImage, std::function< void()> actualizeTabPanes, std::function< void()> actualizeActions)

  Creates the property-editor controller and its synchronization callbacks.
- void **sceneSelectionChanged** () const

  Synchronizes current scene selection into property editor bindings.
- void **onPropertyEditorModelChanged** () const

  Executes post-commit synchronization across model representations and panes.
- void **clearPropertyEditorSelection** () const

  Clears property editor selection/bindings during lifecycle resets.
- void **bindDataDefinitionFromInspector** (ModelDataDefinition *dataDefinition, QObject *graphical↩ Object=nullptr) const

Binds a DataDefinition selected from the inspector tree to the property editor.

- bool **isPostCommitPipelineActive** () const

  Reports whether the deferred global refresh pipeline is active.

17.590.1 Detailed Description

Controller that orchestrates property editor state and scene-selection coupling.
This Phase-6 extraction isolates property editor wiring from MainWindow while preserving the existing compatibility façade methods. It coordinates selection-driven property binding and the deferred refresh cascade required after property commits.
Responsibilities:

- synchronize current scene selection into PropertyEditorGenesys/ObjectPropertyBrowser;
- execute post-edit refresh callbacks for model language, trees, C++ export, and tabs;
- coalesce heavy refresh requests to avoid re-entrant UI update storms.

Boundaries:

- it does not own property objects/editors lifetime (maps are injected);
- it does not alter undo/redo infrastructure or scene command orchestration;
- it does not persist models or execute simulation commands.

The documentation for this class was generated from the following files:

- applications/gui/genesys/controllers/PropertyEditorController.h
- applications/gui/genesys/controllers/PropertyEditorController.cpp

17.593.1 Detailed Description

Base metadata for kernel-side control/response abstractions.
Historically, the experiment layer in GenESyS evolved from the basic ModelSimulation controls toward a more generic mechanism capable of exposing arbitrary getters and setters from model-related classes.
Despite the legacy name, this base currently lives in the simulation kernel and supports kernel-side experiment/control abstractions rather than a user-interface property editor.
The documentation for this class was generated from the following file:

- kernel/simulator/SimulationControlAndResponse.h

17.594 testing::internal::ProtobufPrinter Struct Reference

Static Public Member Functions

- template<typename T , typename = typename std::enable_if< internal::HasDebugStringAndShortDebugString<T>::value>::type> static void **PrintValue** (const T &value, ::std::ostream *os)

Static Public Attributes

- static const size_t **kProtobufOneLinerMaxLength** = 50

The documentation for this struct was generated from the following file:

- gtest/gtest/gtest-printers.h

17.595 ProviderRequest Struct Reference

Input to a single LLM chat-completion call.
`#include <tools/AIAssistant/AIProviderClient_if.h>`

Public Attributes

- std::string **model**

  Provider model identifier.
- std::vector< ChatMessage > **messages**

  Conversation turns.
- double **temperature** = 0.2

  Sampling temperature [0,2].
- unsigned int **maxTokens** = 4096

  Maximum output tokens.
- bool **highReasoningMode** = false

  Request extended reasoning (o-series / Claude thinking).

17.595.1 Detailed Description

Input to a single LLM chat-completion call.
The documentation for this struct was generated from the following file:

- tools/AIAssistant/AIProviderClient_if.h

17.596 ProviderResponse Struct Reference

Output from a single LLM chat-completion call.
`#include <tools/AIAssistant/AIProviderClient_if.h>`

Public Attributes

- bool **success** = false

  `true` *when the provider returned a valid completion.*
- std::string **content**

  Model reply text. Empty on failure.
- std::string **errorMessage**

  Provider or transport error description.
- int **httpStatusCode** = 0

  Raw HTTP status (0 when transport not used).
- unsigned int **inputTokens** = 0

  Prompt tokens consumed (0 when unreported).
- unsigned int **outputTokens** = 0

  Completion tokens produced (0 when unreported).

17.596.1 Detailed Description

Output from a single LLM chat-completion call.
The documentation for this struct was generated from the following file:

- tools/AIAssistant/AIProviderClient_if.h

17.597 testing::internal::ProxyTypeList< Ts > Struct Template Reference

  virtual public methods

Public Member Functions inherited from ModelComponent

- ModelComponent (Model *model, std::string componentTypename, std::string name="")

  constructors
- virtual ~**ModelComponent** ()

  Releases component-owned resources and unregisters it from the model.
- ConnectionManager * getConnectionManager () const

  new public user methods for this component
- void connectTo (ModelComponent *component, unsigned int inputPortNumber=0)

  Connects this component to another component.
- bool hasBreakpointAt ()

  Indicates whether a simulation breakpoint is set on this component.
- void setDescription (std::string _description)

  Updates the free-form description shown by the GUI.
- std::string getDescription () const

  Returns the free-form description associated with this component.
- void remove (ModelComponent *comp)

  Removes a connected component from this component.

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model *model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ~**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model * getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.

- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition * getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition * > * getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition * > * getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl * > * getSimulationControls () const

  Returns the simulation controls owned by this data definition.
- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

Static Public Member Functions

- static PluginInformation * **GetPluginInformation** ()
- static ModelComponent * **LoadInstance** (Model *model, PersistenceRecord *fields)
- static ModelDataDefinition * **NewInstance** (Model *model, std::string name="")

Static Public Member Functions inherited from ModelComponent

- static ModelComponent * LoadInstance (Model *model, PersistenceRecord *fields)

  static public methods that must have implementations (Load and New just the same. GetInformation must provide specific infos for the new component
- static bool Check (ModelComponent *component)

  Validates a component instance.
- static void CreateInternalData (ModelComponent *component)

  Creates internal data required by a component instance.
- static void SaveInstance (PersistenceRecord *fields, ModelComponent *component)

  Serializes a component instance into a persistence record.
- static void DispatchEvent (Event *event)

  Dispatches a simulation event to the target component.

Static Public Member Functions inherited from ModelDataDefinition

- static ModelDataDefinition * LoadInstance (Model *model, PersistenceRecord *fields, bool insertIntoModel)

  Loads a model data definition instance from serialized fields.
- static ModelDataDefinition * NewInstance (Model *model, std::string name="")

  Creates a new instance of a data definition using the plugin registry.
- static void SaveInstance (PersistenceRecord *fields, ModelDataDefinition *modeldatum)

  Serializes a data definition instance into a persistence record.
- static bool Check (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Validates a data definition instance.
- static void InitBetweenReplications (ModelDataDefinition *modeldatum)

  Resets simulation-time state between replications.
- static void CreateInternalData (ModelDataDefinition *modeldatum)

  Creates internal and attached data required by this instance.
- static bool CreateRelatedDataElements (ModelDataDefinition *modeldatum, std::string &errorMessage)

  Creates related data and validates the instance in a single call.

Protected Member Functions

- virtual bool _loadInstance (PersistenceRecord *fields) override

  virtual protected method that must be overriden
- virtual void _saveInstance (PersistenceRecord *fields, bool saveDefaultValues) override

  Saves object fields into a serialization structure.
- virtual void _onDispatchEvent (Entity *entity, unsigned int inputPortNumber) override

  Handles a dispatched event for this component type.
- virtual bool _check (std::string &errorMessage) override

  could be overriden by derived classes
- virtual void _initBetweenReplications () override
- virtual void _createNonEditableDataDefinitions () override

Protected Member Functions inherited from ModelDataDefinition

17.598.1 Member Function Documentation

17.598.1.1 _check()

```
bool PythonForG::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.598.1.2 _createNonEditableDataDefinitions()

```
void PythonForG::_createNonEditableDataDefinitions ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.598.1.3 _initBetweenReplications()

```
void PythonForG::_initBetweenReplications ( )  [override], [protected], [virtual]
```

Reimplemented from ModelDataDefinition.

17.598.1.4 _loadInstance()

```
bool PythonForG::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

virtual protected method that must be overriden
Reimplemented from ModelComponent.

17.598.1.5 _onDispatchEvent()

```
void PythonForG::_onDispatchEvent (
            Entity * entity,
            unsigned int inputPortNumber )  [override], [protected], [virtual]
```

Handles a dispatched event for this component type.
This method is only for ModelComponents, not for ModelDataElements.

Parameters

entity	Entity being processed.
inputPortNumber	Input port where the entity arrived.

Implements ModelComponent.

17.598.1.6 _saveInstance()

```
void PythonForG::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelComponent.

17.598.1.7 show()

```
std::string PythonForG::show ( )  [override], [virtual]
```

virtual public methods
Returns a textual representation of this component.

Returns

Human-readable description used for tracing and debugging.

Reimplemented from ModelComponent.
The documentation for this class was generated from the following files:

Public Member Functions inherited from ModelDataDefinition

- ModelDataDefinition (Model ∗model, std::string datadefinitionTypename, std::string name="", bool insert↩ IntoModel=true)

  Creates a model data definition and optionally inserts it into the model.
- virtual ∼**ModelDataDefinition** ()

  Releases resources owned by this data definition.
- Util::identification getId () const

  Returns the unique identifier of this instance.
- void setName (const std::string &name)

  Updates the logical name of this instance.
- const std::string & getName () const

  Returns the logical name of this instance.
- void setLabel (const std::string &label)

  Updates the user-visible label of this instance.
- const std::string & getLabel () const

  Returns the user-visible label of this instance.
- const std::string & getClassname () const

  Returns the runtime class name used by the plugin system.
- Model ∗ getParentModel () const

  Returns the parent model that owns this definition.
- bool isReportStatistics () const

  Indicates whether this data definition contributes report statistics.
- void setReportStatistics (bool reportStatistics)

  Enables or disables report-statistics generation for this definition.
- ModelDataDefinition ∗ getInternalData (const std::string &name) const

  Looks up a named internal child data definition.
- std::map< std::string, ModelDataDefinition ∗ > ∗ getInternalData () const

  Returns the full map of internal child data definitions.
- std::map< std::string, ModelDataDefinition ∗ > ∗ getAttachedData () const

  Returns the full map of attached data definitions.
- bool hasChanged () const

  Indicates whether this instance has been modified since the last reset.
- void setHasChanged (bool hasChanged)

  Updates the changed flag for this data definition.
- unsigned int getLevel () const

  Returns the hierarchical editing context containing this element.
- void setModelLevel (unsigned int _modelLevel)

  Sets this element's hierarchical editing context.
- List< SimulationControl ∗ > ∗ getSimulationControls () const

  Returns the simulation controls owned by this data definition.

- TraceManager::Level getTraceLevelSpecific () const

  Returns the trace level that applies specifically to this definition.
- void setTraceLevelSpecific (TraceManager::Level level)

  Updates the trace level used by this definition.
- void defineTraceLevelSpecific (TraceManager::Level traceLevelspecific, bool traceLevelSpecific↩ Enabled=true)

  Defines the specific trace level and optionally enables it immediately.
- bool isTraceLevelSpecificEnabled () const

  Indicates whether the specific trace level is enabled.
- void setTraceLevelSpecificEnabled (bool traceLevelSpecificEnabled)

  Enables or disables the specific trace level.

17.599.1 Member Function Documentation

17.599.1.1 _check()

```
bool PythonRuntime::_check (
            std::string & errorMessage )  [override], [protected], [virtual]
```

could be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.599.1.2 _loadInstance()

```
bool PythonRuntime::_loadInstance (
            PersistenceRecord * fields )  [override], [protected], [virtual]
```

must be overriden by derived classes
Reimplemented from ModelDataDefinition.

17.599.1.3 _saveInstance()

```
void PythonRuntime::_saveInstance (
            PersistenceRecord * fields,
            bool saveDefaultValues )  [override], [protected], [virtual]
```

Saves object fields into a serialization structure.

Parameters

fields	a table-like structure used for serialization.
saveDefaultValues	indicates whether or not to save fields which are set to their default value.

Reimplemented from ModelDataDefinition.

17.599.1.4 show()

```
std::string PythonRuntime::show ( )  [override], [virtual]
```

Returns a textual representation of this data definition.
Returns the keys of internal ModelDataDefinitions such as counters, statistics collectors and other children needed before model checking.

Returns

Human-readable summary used by traces and debug output.

Reimplemented from ModelDataDefinition.

17.600.1 Detailed Description

The abstract base class for all items in a plot.
In QCustomPlot, items are supplemental graphical elements that are neither plottables (QCPAbstractPlottable) nor axes (QCPAxis). While plottables are always tied to two axes and thus plot coordinates, items can also be placed in absolute coordinates independent of any axes. Each specific item has at least one QCPItemPosition member which controls the positioning. Some items are defined by more than one coordinate and thus have two or more QCPItemPosition members (For example, QCPItemRect has *topLeft* and *bottomRight*).
This abstract base class defines a very basic interface like visibility and clipping. Since this class is abstract, it can't be instantiated. Use one of the subclasses or create a subclass yourself to create new items.
The built-in items are:

QCPItemLine	A line defined by a start and an end point. May have different ending styles on each side (e.g. arrows).
QCPItemStraightLine	A straight line defined by a start and a direction point. Unlike QCPItemLine, the straight line is infinitely long and has no endings.
QCPItemCurve	A curve defined by start, end and two intermediate control points. May have different ending styles on each side (e.g. arrows).
QCPItemRect	A rectangle
QCPItemEllipse	An ellipse
QCPItemPixmap	An arbitrary pixmap

QCPItemText	A text label
QCPItemBracket	A bracket which may be used to reference/highlight certain parts in the plot.
QCPItemTracer	An item that can be attached to a QCPGraph and sticks to its data points, given a key coordinate.

17.600.2 Clipping

Items are by default clipped to the main axis rect (they are only visible inside the axis rect). To make an item visible outside that axis rect, disable clipping via setClipToAxisRect(false).
On the other hand if you want the item to be clipped to a different axis rect, specify it via setClipAxisRect. This clipAxisRect property of an item is only used for clipping behaviour, and in principle is independent of the coordinate axes the item might be tied to via its position members (QCPItemPosition::setAxes). However, it is common that the axis rect for clipping also contains the axes used for the item positions.

17.600.3 Using items

First you instantiate the item you want to use and add it to the plot:
by default, the positions of the item are bound to the x- and y-Axis of the plot. So we can just set the plot coordinates where the line should start/end:
If we don't want the line to be positioned in plot coordinates but a different coordinate system, e.g. absolute pixel positions on the QCustomPlot surface, we need to change the position type like this:
Then we can set the coordinates, this time in pixels:
and make the line visible on the entire QCustomPlot, by disabling clipping to the axis rect:
For more advanced plots, it is even possible to set different types and parent anchors per X/Y coordinate of an item position, using for example QCPItemPosition::setTypeX or QCPItemPosition::setParentAnchorX. For details, see the documentation of QCPItemPosition.

17.600.4 Creating own items

To create an own item, you implement a subclass of QCPAbstractItem. These are the pure virtual functions, you must implement:

- selectTest
- draw

See the documentation of those functions for what they need to do.

17.600.4.1 Allowing the item to be positioned

As mentioned, item positions are represented by QCPItemPosition members. Let's assume the new item shall have only one point as its position (as opposed to two like a rect or multiple like a polygon). You then add a public member of type QCPItemPosition like so:

```
QCPItemPosition * const myPosition;
```

the const makes sure the pointer itself can't be modified from the user of your new item (the QCPItemPosition instance it points to, can be modified, of course). The initialization of this pointer is made easy with the createPosition function. Just assign the return value of this function to each QCPItemPosition in the constructor of your item. createPosition takes a string which is the name of the position, typically this is identical to the variable name. For example, the constructor of QCPItemExample could look like this:

```
QCPItemExample::QCPItemExample(QCustomPlot *parentPlot) :
  QCPAbstractItem(parentPlot),
  myPosition(createPosition("myPosition"))
{
  // other constructor code
}
```

17.600.4.2 The draw function

To give your item a visual representation, reimplement the draw function and use the passed QCPPainter to draw the item. You can retrieve the item position in pixel coordinates from the position member(s) via QCPItemPosition::pixelPosition.

To optimize performance you should calculate a bounding rect first (don't forget to take the pen width into account), check whether it intersects the clipRect, and only draw the item at all if this is the case.

17.600.4.3 The selectTest function

Your implementation of the selectTest function may use the helpers QCPVector2D::distanceSquaredToLine and rectDistance. With these, the implementation of the selection test becomes significantly simpler for most items. See the documentation of selectTest for what the function parameters mean and what the function should return.

17.600.4.4 Providing anchors

Providing anchors (QCPItemAnchor) starts off like adding a position. First you create a public member, e.g.
`QCPItemAnchor * const bottom;`
and create it in the constructor with the createAnchor function, assigning it a name and an anchor id (an integer enumerating all anchors on the item, you may create an own enum for this). Since anchors can be placed anywhere, relative to the item's position(s), your item needs to provide the position of every anchor with the reimplementation of the anchorPixelPosition(int anchorId) function.
In essence the QCPItemAnchor is merely an intermediary that itself asks your item for the pixel position when anything attached to the anchor needs to know the coordinates.

17.600.5 Constructor & Destructor Documentation

17.600.5.1 QCPAbstractItem()

```
QCPAbstractItem::QCPAbstractItem (
            QCustomPlot * parentPlot )  [explicit]
```
Base class constructor which initializes base class members.

17.600.6 Member Function Documentation

17.600.6.1 anchor()

```
QCPItemAnchor * QCPAbstractItem::anchor (
            const QString & name ) const
```
Returns the QCPItemAnchor with the specified *name*. If this item doesn't have an anchor by that name, returns `nullptr`.
This function provides an alternative way to access item anchors. Normally, you access anchors direcly by their member pointers (which typically have the same variable name as *name*).

See also

anchors, position

17.600.6.2 anchors()

```
QList< QCPItemAnchor * > QCPAbstractItem::anchors ( ) const  [inline]
```
Returns all anchors of the item in a list. Note that since a position (QCPItemPosition) is always also an anchor, the list will also contain the positions of this item.

See also

positions, anchor

17.600.6.3 applyDefaultAntialiasingHint()

```
void QCPAbstractItem::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```
Implements QCPLayerable.

17.600.6.4 clipRect()

```
QRect QCPAbstractItem::clipRect ( ) const  [protected], [virtual]
```
Reimplemented from QCPLayerable.

17.600.6.5 deselectEvent()

```
void QCPAbstractItem::deselectEvent (
            bool * selectionStateChanged )  [protected], [virtual]
```
Reimplemented from QCPLayerable.

17.600.6.6 draw()

```
void QCPAbstractItem::draw (
            QCPPainter * painter )  [protected], [pure virtual]
```
Implements QCPLayerable.

17.600.6.7 hasAnchor()

```
bool QCPAbstractItem::hasAnchor (
            const QString & name ) const
```
Returns whether this item has an anchor with the specified *name*.
Note that you can check for positions with this function, too. This is because every position is also an anchor (QCPItemPosition inherits from QCPItemAnchor).

See also

anchor, position

17.600.6.8 position()

```
QCPItemPosition * QCPAbstractItem::position (
            const QString & name ) const
```
Returns the QCPItemPosition with the specified *name*. If this item doesn't have a position by that name, returns `nullptr`.
This function provides an alternative way to access item positions. Normally, you access positions direcly by their member pointers (which typically have the same variable name as *name*).

See also

positions, anchor

17.600.6.9 positions()

```
QList< QCPItemPosition * > QCPAbstractItem::positions ( ) const  [inline]
```
Returns all positions of the item in a list.

See also

anchors, position

17.600.6.10 selectEvent()

```
void QCPAbstractItem::selectEvent (
            QMouseEvent * event,
            bool additive,
            const QVariant & details,
            bool * selectionStateChanged )  [protected], [virtual]
```
Reimplemented from QCPLayerable.

17.600.6.11 selectionCategory()

```
QCP::Interaction QCPAbstractItem::selectionCategory ( ) const  [protected], [virtual]
```
Reimplemented from QCPLayerable.

17.600.6.12 selectionChanged

```
void QCPAbstractItem::selectionChanged (
            bool selected )  [signal]
```
This signal is emitted when the selection state of this item has changed, either by user interaction or by a direct call to setSelected.

17.600.6.13 selectTest()

```
virtual double QCPAbstractItem::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [pure virtual]
```
This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

See also

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Reimplemented from QCPLayerable.
Implemented in QCPItemStraightLine, QCPItemLine, QCPItemCurve, QCPItemRect, QCPItemText, QCPItemEllipse, QCPItemPixmap, QCPItemTracer, and QCPItemBracket.

17.600.6.14 setClipAxisRect()

```
void QCPAbstractItem::setClipAxisRect (
            QCPAxisRect * rect )
```
Sets the clip axis rect. It defines the rect that will be used to clip the item when setClipToAxisRect is set to true.

See also

setClipToAxisRect

17.600.6.15 setClipToAxisRect()

```
void QCPAbstractItem::setClipToAxisRect (
            bool clip )
```

Sets whether the item shall be clipped to an axis rect or whether it shall be visible on the entire QCustomPlot. The axis rect can be set with setClipAxisRect.

See also

setClipAxisRect

17.600.6.16 setSelectable()

```
void QCPAbstractItem::setSelectable (
            bool selectable )
```

Sets whether the user can (de-)select this item by clicking on the QCustomPlot surface. (When QCustomPlot::setInteractions contains QCustomPlot::iSelectItems.)
However, even when *selectable* was set to false, it is possible to set the selection manually, by calling setSelected.

See also

QCustomPlot::setInteractions, setSelected

17.600.6.17 setSelected()

```
void QCPAbstractItem::setSelected (
            bool selected )
```

Sets whether this item is selected or not. When selected, it might use a different visual appearance (e.g. pen and brush), this depends on the specific item though.
The entire selection mechanism for items is handled automatically when QCustomPlot::setInteractions contains QCustomPlot::iSelectItems. You only need to call this function when you wish to change the selection state manually.
This function can change the selection state even when setSelectable was set to false.
emits the selectionChanged signal when *selected* is different from the previous selection state.

17.601.1 Detailed Description

The abstract base class for all entries in a QCPLegend.
It defines a very basic interface for entries in a QCPLegend. For representing plottables in the legend, the subclass QCPPlottableLegendItem is more suitable.
Only derive directly from this class when you need absolute freedom (e.g. a custom legend entry that's not even associated with a plottable).
You must implement the following pure virtual functions:

- draw (from QCPLayerable)

You inherit the following members you may use:

QCPLegend *__mParentLegend__	A pointer to the parent QCPLegend.
QFont **mFont**	The generic font of the item. You should use this font for all or at least the most prominent text of the item.

17.601.2 Constructor & Destructor Documentation

17.601.2.1 QCPAbstractLegendItem()

```
QCPAbstractLegendItem::QCPAbstractLegendItem (
            QCPLegend * parent )  [explicit]
```

Constructs a QCPAbstractLegendItem and associates it with the QCPLegend *parent*. This does not cause the item to be added to *parent*, so QCPLegend::addItem must be called separately.

17.601.3 Member Function Documentation

17.601.3.1 applyDefaultAntialiasingHint()

```
void QCPAbstractLegendItem::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Reimplemented from QCPLayoutElement.

17.601.3.2 clipRect()

```
QRect QCPAbstractLegendItem::clipRect ( ) const  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.601.3.3 deselectEvent()

```
void QCPAbstractLegendItem::deselectEvent (
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.601.3.4 draw()

```
virtual void QCPAbstractLegendItem::draw (
            QCPPainter * painter )  [protected], [pure virtual]
```

Reimplemented from QCPLayoutElement.

17.601.3.5 selectEvent()

```
void QCPAbstractLegendItem::selectEvent (
            QMouseEvent * event,
            bool additive,
            const QVariant & details,
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.601.3.6 selectionCategory()

```
QCP::Interaction QCPAbstractLegendItem::selectionCategory ( ) const  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.601.3.7 selectionChanged

```
void QCPAbstractLegendItem::selectionChanged (
            bool selected )  [signal]
```

This signal is emitted when the selection state of this legend item has changed, either by user interaction or by a direct call to setSelected.

17.601.3.8 selectTest()

```
double QCPAbstractLegendItem::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Layout elements are sensitive to events inside their outer rect. If *pos* is within the outer rect, this method returns a value corresponding to 0.99 times the parent plot's selection tolerance. However, layout elements are not selectable by default. So if *onlySelectable* is true, -1.0 is returned.
See QCPLayerable::selectTest for a general explanation of this virtual method.
QCPLayoutElement subclasses may reimplement this method to provide more specific selection test behaviour.
Reimplemented from QCPLayoutElement.

17.601.3.9 setFont()

```
void QCPAbstractLegendItem::setFont (
            const QFont & font )
```

Sets the default font of this specific legend item to *font*.

See also

setTextColor, QCPLegend::setFont

17.601.3.10 setSelectable()

```
void QCPAbstractLegendItem::setSelectable (
            bool selectable )
```

Sets whether this specific legend item is selectable.

See also

setSelectedParts, QCustomPlot::setInteractions

17.601.3.11 setSelected()

```
void QCPAbstractLegendItem::setSelected (
            bool selected )
```

Sets whether this specific legend item is selected.
It is possible to set the selection state of this item by calling this function directly, even if setSelectable is set to false.

See also

setSelectableParts, QCustomPlot::setInteractions

17.601.3.12 setSelectedFont()

```
void QCPAbstractLegendItem::setSelectedFont (
            const QFont & font )
```

When this legend item is selected, *font* is used to draw generic text, instead of the normal font set with setFont.

See also

setFont, QCPLegend::setSelectedFont

17.601.3.13 setSelectedTextColor()

```
void QCPAbstractLegendItem::setSelectedTextColor (
            const QColor & color )
```

When this legend item is selected, *color* is used to draw generic text, instead of the normal color set with setTextColor.

See also

setTextColor, QCPLegend::setSelectedTextColor

17.601.3.14 setTextColor()

```
void QCPAbstractLegendItem::setTextColor (
            const QColor & color )
```

Sets the default text color of this specific legend item to *color*.

See also

setFont, QCPLegend::setTextColor

- double **mDevicePixelRatio**
- bool **mInvalidated**

17.602.1 Detailed Description

The abstract base class for paint buffers, which define the rendering backend.
This abstract base class defines the basic interface that a paint buffer needs to provide in order to be usable by QCustomPlot.
A paint buffer manages both a surface to draw onto, and the matching paint device. The size of the surface can be changed via setSize. External classes (QCustomPlot and QCPLayer) request a painter via startPainting and then perform the draw calls. Once the painting is complete, donePainting is called, so the paint buffer implementation can do clean up if necessary. Before rendering a frame, each paint buffer is usually filled with a color using clear (usually the color is `Qt::transparent`), to remove the contents of the previous frame.
The simplest paint buffer implementation is QCPPaintBufferPixmap which allows regular software rendering via the raster engine. Hardware accelerated rendering via pixel buffers and frame buffer objects is provided by QCPPaint↩ BufferGlPbuffer and QCPPaintBufferGlFbo. They are used automatically if QCustomPlot::setOpenGl is enabled.

17.602.2 Constructor & Destructor Documentation

17.602.2.1 QCPAbstractPaintBuffer()

```
QCPAbstractPaintBuffer::QCPAbstractPaintBuffer (
            const QSize & size,
            double devicePixelRatio )  [explicit]
```

Creates a paint buffer and initializes it with the provided *size* and *devicePixelRatio*.
Subclasses must call their reallocateBuffer implementation in their respective constructors.

17.602.3 Member Function Documentation

17.602.3.1 clear()

```
void QCPAbstractPaintBuffer::clear (
            const QColor & color )  [pure virtual]
```

Fills the entire buffer with the provided *color*. To have an empty transparent buffer, use the named color `Qt::transparent`.
This method must not be called if there is currently a painter (acquired with startPainting) active.
Implemented in QCPPaintBufferPixmap.

17.602.3.2 donePainting()

```
void QCPAbstractPaintBuffer::donePainting ( )  [inline], [virtual]
```

If you have acquired a QCPPainter to paint onto this paint buffer via startPainting, call this method as soon as you are done with the painting operations and have deleted the painter.
paint buffer subclasses may use this method to perform any type of cleanup that is necessary. The default implementation does nothing.

17.602.3.3 draw()

```
void QCPAbstractPaintBuffer::draw (
            QCPPainter * painter ) const  [pure virtual]
```

Draws the contents of this buffer with the provided *painter*. This is the method that is used to finally join all paint buffers and draw them onto the screen.
Implemented in QCPPaintBufferPixmap.

17.602.3.4 reallocateBuffer()

```
void QCPAbstractPaintBuffer::reallocateBuffer ( )  [protected], [pure virtual]
```

Reallocates the internal buffer with the currently configured size (setSize) and device pixel ratio, if applicable (setDevicePixelRatio). It is called as soon as any of those properties are changed on this paint buffer.

Note

> Subclasses of QCPAbstractPaintBuffer must call their reimplementation of this method in their constructor, to perform the first allocation (this can not be done by the base class because calling pure virtual methods in base class constructors is not possible).

Implemented in QCPPaintBufferPixmap.

17.602.3.5 setDevicePixelRatio()

```
void QCPAbstractPaintBuffer::setDevicePixelRatio (
            double ratio )
```

Sets the device pixel ratio to *ratio*. This is useful to render on high-DPI output devices. The ratio is automatically set to the device pixel ratio used by the parent QCustomPlot instance.
The buffer is reallocated (by calling reallocateBuffer), so any painters that were obtained by startPainting are invalidated and must not be used after calling this method.

Note

This method is only available for Qt versions 5.4 and higher.

17.602.3.6 setInvalidated()

```
void QCPAbstractPaintBuffer::setInvalidated (
            bool invalidated = true )
```

Sets the invalidated flag to *invalidated*.
This mechanism is used internally in conjunction with isolated replotting of QCPLayer instances (in QCPLayer::lmBuffered mode). If QCPLayer::replot is called on a buffered layer, i.e. an isolated repaint of only that layer (and its dedicated paint buffer) is requested, QCustomPlot will decide depending on the invalidated flags of other paint buffers whether it also replots them, instead of only the layer on which the replot was called.
The invalidated flag is set to true when QCPLayer association has changed, i.e. if layers were added or removed from this buffer, or if they were reordered. It is set to false as soon as all associated QCPLayer instances are drawn onto the buffer.
Under normal circumstances, it is not necessary to manually call this method.

17.602.3.7 setSize()

```
void QCPAbstractPaintBuffer::setSize (
            const QSize & size )
```

Sets the paint buffer size.
The buffer is reallocated (by calling reallocateBuffer), so any painters that were obtained by startPainting are invalidated and must not be used after calling this method.
If *size* is already the current buffer size, this method does nothing.

17.602.3.8 startPainting()

```
QCPPainter * QCPAbstractPaintBuffer::startPainting ( )  [pure virtual]
```

Returns a QCPPainter which is ready to draw to this buffer. The ownership and thus the responsibility to delete the painter after the painting operations are complete is given to the caller of this method.
Once you are done using the painter, delete the painter and call donePainting.
While a painter generated with this method is active, you must not call setSize, setDevicePixelRatio or clear.
This method may return 0, if a painter couldn't be activated on the buffer. This usually indicates a problem with the respective painting backend.
Implemented in QCPPaintBufferPixmap.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.603 QCPAbstractPlottable Class Reference

The abstract base class for all data representing objects in a plot.

17.603.1 Detailed Description

The abstract base class for all data representing objects in a plot.
It defines a very basic interface like name, pen, brush, visibility etc. Since this class is abstract, it can't be instantiated. Use one of the subclasses or create a subclass yourself to create new ways of displaying data (see "Creating own plottables" below). Plottables that display one-dimensional data (i.e. data points have a single key dimension and one or multiple values at each key) are based off of the template subclass QCPAbstractPlottable1D, see details there.
All further specifics are in the subclasses, for example:

- A normal graph with possibly a line and/or scatter points QCPGraph (typically created with QCustomPlot::addGraph)
- A parametric curve: QCPCurve
- A bar chart: QCPBars
- A statistical box plot: QCPStatisticalBox
- A color encoded two-dimensional map: QCPColorMap
- An OHLC/Candlestick chart: QCPFinancial

17.603.2 Creating own plottables

Subclassing directly from QCPAbstractPlottable is only recommended if you wish to display two-dimensional data like QCPColorMap, i.e. two logical key dimensions and one (or more) data dimensions. If you want to display data with only one logical key dimension, you should rather derive from QCPAbstractPlottable1D.
If subclassing QCPAbstractPlottable directly, these are the pure virtual functions you must implement:

- selectTest
- draw
- drawLegendIcon
- getKeyRange
- getValueRange

See the documentation of those functions for what they need to do.
For drawing your plot, you can use the coordsToPixels functions to translate a point in plot coordinates to pixel coordinates. This function is quite convenient, because it takes the orientation of the key and value axes into account for you (x and y are swapped when the key axis is vertical and the value axis horizontal). If you are worried about performance (i.e. you need to translate many points in a loop like QCPGraph), you can directly use QCPAxis::coordToPixel. However, you must then take care about the orientation of the axis yourself.
Here are some important members you inherit from QCPAbstractPlottable:

QCustomPlot *__mParentPlot__	A pointer to the parent QCustomPlot instance. The parent plot is inferred from the axes that are passed in the constructor.
QString __mName__	The name of the plottable.
QPen __mPen__	The generic pen of the plottable. You should use this pen for the most prominent data representing lines in the plottable (e.g QCPGraph uses this pen for its graph lines and scatters)
QBrush __mBrush__	The generic brush of the plottable. You should use this brush for the most prominent fillable structures in the plottable (e.g. QCPGraph uses this brush to control filling under the graph)
QPointer<QCPAxis> __mKeyAxis__, __mValueAxis__	The key and value axes this plottable is attached to. Call their QCPAxis::coordToPixel functions to translate coordinates to pixels in either the key or value dimension. Make sure to check whether the pointer is `nullptr` before using it. If one of the axes is null, don't draw the plottable.

QCPSelectionDecorator **mSelectionDecorator**	The currently set selection decorator which specifies how selected data of the plottable shall be drawn and decorated. When drawing your data, you must consult this decorator for the appropriate pen/brush before drawing unselected/selected data segments. Finally, you should call its QCPSelectionDecorator::drawDecoration method at the end of your draw implementation.
QCP::SelectionType **mSelectable**	In which composition, if at all, this plottable's data may be selected. Enforcing this setting on the data selection is done by QCPAbstractPlottable automatically.
QCPDataSelection **mSelection**	Holds the current selection state of the plottable's data, i.e. the selected data ranges (QCPDataRange).

17.603.3 Constructor & Destructor Documentation

17.603.3.1 QCPAbstractPlottable()

```
QCPAbstractPlottable::QCPAbstractPlottable (
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )
```

Constructs an abstract plottable which uses *keyAxis* as its key axis ("x") and *valueAxis* as its value axis ("y"). *key↩ Axis* and *valueAxis* must reside in the same QCustomPlot instance and have perpendicular orientations. If either of these restrictions is violated, a corresponding message is printed to the debug output (qDebug), the construction is not aborted, though.
Since QCPAbstractPlottable is an abstract class that defines the basic interface to plottables, it can't be directly instantiated.
You probably want one of the subclasses like QCPGraph or QCPCurve instead.

17.603.4 Member Function Documentation

17.603.4.1 addToLegend() [1/2]

```
bool QCPAbstractPlottable::addToLegend ( )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds this plottable to the legend of the parent QCustomPlot (QCustomPlot::legend).

See also

removeFromLegend

17.603.4.2 addToLegend() [2/2]

```
bool QCPAbstractPlottable::addToLegend (
            QCPLegend * legend )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds this plottable to the specified *legend*.
Creates a QCPPlottableLegendItem which is inserted into the legend. Returns true on success, i.e. when the legend exists and a legend item associated with this plottable isn't already in the legend.
If the plottable needs a more specialized representation in the legend, you can create a corresponding subclass of QCPPlottableLegendItem and add it to the legend manually instead of calling this method.

See also

removeFromLegend, QCPLegend::addItem

17.603.4.3 applyDefaultAntialiasingHint()

```
void QCPAbstractPlottable::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Implements QCPLayerable.

17.603.4.4 clipRect()

```
QRect QCPAbstractPlottable::clipRect ( ) const  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.603.4.5 coordsToPixels() [1/2]

```
const QPointF QCPAbstractPlottable::coordsToPixels (
            double key,
            double value ) const
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Transforms the given *key* and *value* to pixel coordinates and returns them in a QPointF.

17.603.4.6 coordsToPixels() [2/2]

```
void QCPAbstractPlottable::coordsToPixels (
            double key,
            double value,
            double & x,
            double & y ) const
```

Convenience function for transforming a key/value pair to pixels on the QCustomPlot surface, taking the orientations of the axes associated with this plottable into account (e.g. whether key represents x or y).
key and *value* are transformed to the coodinates in pixels and are written to *x* and *y*.

See also

pixelsToCoords, QCPAxis::coordToPixel

17.603.4.7 deselectEvent()

```
void QCPAbstractPlottable::deselectEvent (
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.603.4.8 draw()

```
virtual void QCPAbstractPlottable::draw (
            QCPPainter * painter )  [protected], [pure virtual]
```

Implements QCPLayerable.

17.603.4.9 getKeyRange()

```
QCPRange QCPAbstractPlottable::getKeyRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth ) const  [pure virtual]
```

Returns the coordinate range that all data in this plottable span in the key axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSignDomain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getValueRange

Implemented in QCPGraph, QCPCurve, QCPBars, QCPStatisticalBox, QCPColorMap, QCPFinancial, and QCPErrorBars.

17.603.4.10 getValueRange()

```
QCPRange QCPAbstractPlottable::getValueRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth,
            const QCPRange & inKeyRange = QCPRange() ) const  [pure virtual]
```

Returns the coordinate range that the data points in the specified key range (*inKeyRange*) span in the value axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSign↩ Domain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
If *inKeyRange* has both lower and upper bound set to zero (is equal to `QCPRange()`), all data points are considered, without any restriction on the keys.
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getKeyRange

Implemented in QCPGraph, QCPCurve, QCPBars, QCPStatisticalBox, QCPColorMap, QCPFinancial, and QCPErrorBars.

17.603.4.11 interface1D()

```
QCPPlottableInterface1D * QCPAbstractPlottable::interface1D ( )  [inline], [virtual]
```

If this plottable is a one-dimensional plottable, i.e. it implements the QCPPlottableInterface1D, returns the *this* pointer with that type. Otherwise (e.g. in the case of a QCPColorMap) returns zero.
You can use this method to gain read access to data coordinates while holding a pointer to the abstract base class only.
Reimplemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< Q QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat and QCPErrorBars.

17.603.4.12 pixelsToCoords() [1/2]

```
void QCPAbstractPlottable::pixelsToCoords (
            const QPointF & pixelPos,
            double & key,
            double & value ) const
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Returns the pixel input *pixelPos* as plot coordinates *key* and *value*.

17.603.4.13 pixelsToCoords() [2/2]

```
void QCPAbstractPlottable::pixelsToCoords (
            double x,
            double y,
            double & key,
            double & value ) const
```

Convenience function for transforming a x/y pixel pair on the QCustomPlot surface to plot coordinates, taking the orientations of the axes associated with this plottable into account (e.g. whether key represents x or y).
x and *y* are transformed to the plot coodinates and are written to *key* and *value*.

See also

coordsToPixels, QCPAxis::coordToPixel

17.603.4.14 removeFromLegend() [1/2]

```
bool QCPAbstractPlottable::removeFromLegend ( ) const
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Removes the plottable from the legend of the parent QCustomPlot.

See also

addToLegend

17.603.4.15 removeFromLegend() [2/2]

```
bool QCPAbstractPlottable::removeFromLegend (
            QCPLegend * legend ) const
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Removes the plottable from the specifed *legend*. This means the QCPPlottableLegendItem that is associated with this plottable is removed.
Returns true on success, i.e. if the legend exists and a legend item associated with this plottable was found and removed.

See also

addToLegend, QCPLegend::removeItem

17.603.4.16 rescaleAxes()

```
void QCPAbstractPlottable::rescaleAxes (
            bool onlyEnlarge = false ) const
```

Rescales the key and value axes associated with this plottable to contain all displayed data, so the whole plottable is visible. If the scaling of an axis is logarithmic, rescaleAxes will make sure not to rescale to an illegal range i.e. a range containing different signs and/or zero. Instead it will stay in the current sign domain and ignore all parts of the plottable that lie outside of that domain.
onlyEnlarge makes sure the ranges are only expanded, never reduced. So it's possible to show multiple plottables in their entirety by multiple calls to rescaleAxes where the first call has *onlyEnlarge* set to false (the default), and all subsequent set to true.

See also

rescaleKeyAxis, rescaleValueAxis, QCustomPlot::rescaleAxes, QCPAxis::rescale

17.603.4.17 rescaleKeyAxis()

```
void QCPAbstractPlottable::rescaleKeyAxis (
            bool onlyEnlarge = false ) const
```

Rescales the key axis of the plottable so the whole plottable is visible.
See rescaleAxes for detailed behaviour.

17.603.4.18 rescaleValueAxis()

```
void QCPAbstractPlottable::rescaleValueAxis (
            bool onlyEnlarge = false,
            bool inKeyRange = false ) const
```

Rescales the value axis of the plottable so the whole plottable is visible. If *inKeyRange* is set to true, only the data points which are in the currently visible key axis range are considered.
Returns true if the axis was actually scaled. This might not be the case if this plottable has an invalid range, e.g. because it has no data points.
See rescaleAxes for detailed behaviour.

17.603.4.19 selectableChanged

```
void QCPAbstractPlottable::selectableChanged (
            QCP::SelectionType selectable ) [signal]
```

This signal is emitted when the selectability of this plottable has changed.

See also

setSelectable

17.603.4.20 selected()

```
bool QCPAbstractPlottable::selected ( ) const [inline]
```

Returns true if there are any data points of the plottable currently selected. Use selection to retrieve the current QCPDataSelection.

17.603.4.21 selectEvent()

```
void QCPAbstractPlottable::selectEvent (
            QMouseEvent * event,
            bool additive,
            const QVariant & details,
            bool * selectionStateChanged ) [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.603.4.22 selection()

```
QCPDataSelection QCPAbstractPlottable::selection ( ) const [inline]
```

Returns a QCPDataSelection encompassing all the data points that are currently selected on this plottable.

See also

selected, setSelection, setSelectable

17.603.4.23 selectionCategory()

```
QCP::Interaction QCPAbstractPlottable::selectionCategory ( ) const [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.603.4.24 selectionChanged [1/2]

```
void QCPAbstractPlottable::selectionChanged (
            bool selected ) [signal]
```

This signal is emitted when the selection state of this plottable has changed, either by user interaction or by a direct call to setSelection. The parameter *selected* indicates whether there are any points selected or not.

See also

selectionChanged(const QCPDataSelection &selection)

17.603.4.25 selectionChanged [2/2]

```
void QCPAbstractPlottable::selectionChanged (
            const QCPDataSelection & selection )  [signal]
```

This signal is emitted when the selection state of this plottable has changed, either by user interaction or by a direct call to setSelection. The parameter *selection* holds the currently selected data ranges.

See also

selectionChanged(bool selected)

17.603.4.26 selectionDecorator()

```
QCPSelectionDecorator * QCPAbstractPlottable::selectionDecorator ( ) const  [inline]
```

Provides access to the selection decorator of this plottable. The selection decorator controls how selected data ranges are drawn (e.g. their pen color and fill), see QCPSelectionDecorator for details.
If you wish to use an own QCPSelectionDecorator subclass, pass an instance of it to setSelectionDecorator.

17.603.4.27 selectTest()

```
virtual double QCPAbstractPlottable::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [pure virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

See also

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Reimplemented from QCPLayerable.
Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP
QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat
QCPGraph, QCPCurve, QCPBars, QCPStatisticalBox, QCPColorMap, QCPFinancial, and QCPErrorBars.

17.603.4.28 setAntialiasedFill()

```
void QCPAbstractPlottable::setAntialiasedFill (
            bool enabled )
```

Sets whether fills of this plottable are drawn antialiased or not.

Note that this setting may be overridden by QCustomPlot::setAntialiasedElements and QCustomPlot::setNotAntialiasedElements.

17.603.4.29 setAntialiasedScatters()

```
void QCPAbstractPlottable::setAntialiasedScatters (
            bool enabled )
```

Sets whether the scatter symbols of this plottable are drawn antialiased or not.
Note that this setting may be overridden by QCustomPlot::setAntialiasedElements and QCustomPlot::setNotAntialiasedElements.

17.603.4.30 setBrush()

```
void QCPAbstractPlottable::setBrush (
            const QBrush & brush )
```

The brush is used to draw basic fills of the plottable representation in the plot. The Fill can be a color, gradient or texture, see the usage of QBrush.
For example, the QCPGraph subclass draws the fill under the graph with this brush, when it's not set to Qt::NoBrush.

See also

setPen

17.603.4.31 setKeyAxis()

```
void QCPAbstractPlottable::setKeyAxis (
            QCPAxis * axis )
```

The key axis of a plottable can be set to any axis of a QCustomPlot, as long as it is orthogonal to the plottable's value axis. This function performs no checks to make sure this is the case. The typical mathematical choice is to use the x-axis (QCustomPlot::xAxis) as key axis and the y-axis (QCustomPlot::yAxis) as value axis.
Normally, the key and value axes are set in the constructor of the plottable (or QCustomPlot::addGraph when working with QCPGraphs through the dedicated graph interface).

See also

setValueAxis

17.603.4.32 setName()

```
void QCPAbstractPlottable::setName (
            const QString & name )
```

The name is the textual representation of this plottable as it is displayed in the legend (QCPLegend). It may contain any UTF-8 characters, including newlines.

17.603.4.33 setPen()

```
void QCPAbstractPlottable::setPen (
            const QPen & pen )
```

The pen is used to draw basic lines that make up the plottable representation in the plot.
For example, the QCPGraph subclass draws its graph lines with this pen.

See also

setBrush

17.603.4.34 setSelectable()

```
void QCPAbstractPlottable::setSelectable (
            QCP::SelectionType selectable )
```

Sets whether and to which granularity this plottable can be selected.
A selection can happen by clicking on the QCustomPlot surface (When QCustomPlot::setInteractions contains QCP::iSelectPlottables), by dragging a selection rect (When QCustomPlot::setSelectionRectMode is QCP::srmSelect), or programmatically by calling setSelection.

See also

setSelection, QCP::SelectionType

17.603.4.35 setSelection()

```
void QCPAbstractPlottable::setSelection (
            QCPDataSelection selection )
```

Sets which data ranges of this plottable are selected. Selected data ranges are drawn differently (e.g. color) in the plot. This can be controlled via the selection decorator (see selectionDecorator).
The entire selection mechanism for plottables is handled automatically when QCustomPlot::setInteractions contains iSelectPlottables. You only need to call this function when you wish to change the selection state programmatically.
Using setSelectable you can further specify for each plottable whether and to which granularity it is selectable. If *selection* is not compatible with the current QCP::SelectionType set via setSelectable, the resulting selection will be adjusted accordingly (see QCPDataSelection::enforceType).
emits the selectionChanged signal when *selected* is different from the previous selection state.

See also

setSelectable, selectTest

17.603.4.36 setSelectionDecorator()

```
void QCPAbstractPlottable::setSelectionDecorator (
            QCPSelectionDecorator * decorator )
```

Use this method to set an own QCPSelectionDecorator (subclass) instance. This allows you to customize the visual representation of selected data ranges further than by using the default QCPSelectionDecorator.
The plottable takes ownership of the *decorator*.
The currently set decorator can be accessed via selectionDecorator.

17.603.4.37 setValueAxis()

```
void QCPAbstractPlottable::setValueAxis (
            QCPAxis * axis )
```

The value axis of a plottable can be set to any axis of a QCustomPlot, as long as it is orthogonal to the plottable's key axis. This function performs no checks to make sure this is the case. The typical mathematical choice is to use the x-axis (QCustomPlot::xAxis) as key axis and the y-axis (QCustomPlot::yAxis) as value axis.
Normally, the key and value axes are set in the constructor of the plottable (or QCustomPlot::addGraph when working with QCPGraphs through the dedicated graph interface).

17.604.1 Detailed Description

template<class DataType>
class QCPAbstractPlottable1D< DataType >

A template base class for plottables with one-dimensional data.
This template class derives from QCPAbstractPlottable and from the abstract interface QCPPlottableInterface1D. It serves as a base class for all one-dimensional data (i.e. data with one key dimension), such as QCPGraph and QCPCurve.
The template parameter *DataType* is the type of the data points of this plottable (e.g. QCPGraphData or QCPCurveData). The main purpose of this base class is to provide the member *mDataContainer* (a shared pointer to a QCPDataContainer<DataType>) and implement the according virtual methods of the QCPPlottableInterface1D, such that most subclassed plottables don't need to worry about this anymore.
Further, it provides a convenience method for retrieving selected/unselected data segments via getDataSegments. This is useful when subclasses implement their draw method and need to draw selected segments with a different pen/brush than unselected segments (also see QCPSelectionDecorator).
This class implements basic functionality of QCPAbstractPlottable::selectTest and QCPPlottableInterface1D::selectTestRect, assuming point-like data points, based on the 1D data interface. In spite of that, most plottable subclasses will want to reimplement those methods again, to provide a more accurate hit test based on their specific data visualization geometry.

17.604.2 Constructor & Destructor Documentation

17.604.2.1 QCPAbstractPlottable1D()

```
template<class DataType >
QCPAbstractPlottable1D< DataType >::QCPAbstractPlottable1D (
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )
```

Forwards *keyAxis* and *valueAxis* to the QCPAbstractPlottable constructor and allocates the *mDataContainer*.

17.604.3 Member Function Documentation

17.604.3.1 dataCount()

```
template<class DataType >
int QCPAbstractPlottable1D< DataType >::dataCount ( ) const  [virtual]
```

Returns the number of data points of the plottable.
Implements QCPPlottableInterface1D.

17.604.3.2 dataMainKey()

```
template<class DataType >
double QCPAbstractPlottable1D< DataType >::dataMainKey (
            int index ) const  [virtual]
```

Returns the main key of the data point at the given *index*.
What the main key is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implements QCPPlottableInterface1D.

17.604.3.3 dataMainValue()

```
template<class DataType >
double QCPAbstractPlottable1D< DataType >::dataMainValue (
            int index ) const  [virtual]
```

Returns the main value of the data point at the given *index*.
What the main value is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implements QCPPlottableInterface1D.

17.604.3.4 dataPixelPosition()

```
template<class DataType >
QPointF QCPAbstractPlottable1D< DataType >::dataPixelPosition (
            int index ) const  [virtual]
```

Returns the pixel position on the widget surface at which the data point at the given *index* appears.
Usually this corresponds to the point of dataMainKey/ dataMainValue, in pixel coordinates. However, depending on the plottable, this might be a different apparent position than just a coord-to-pixel transform of those values. For example, QCPBars apparent data values can be shifted depending on their stacking, bar grouping or configured base value.
Implements QCPPlottableInterface1D.
Reimplemented in QCPBars.

17.604.3.5 dataSortKey()

```
template<class DataType >
double QCPAbstractPlottable1D< DataType >::dataSortKey (
            int index ) const  [virtual]
```

Returns the sort key of the data point at the given *index*.
What the sort key is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.

Implements QCPPlottableInterface1D.

17.604.3.6 dataValueRange()

```
template<class DataType >
QCPRange QCPAbstractPlottable1D< DataType >::dataValueRange (
            int index ) const  [virtual]
```

Returns the value range of the data point at the given *index*.
What the value range is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implements QCPPlottableInterface1D.

17.604.3.7 drawPolyline()

```
template<class DataType >
void QCPAbstractPlottable1D< DataType >::drawPolyline (
            QCPPainter * painter,
            const QVector< QPointF > & lineData ) const  [protected]
```

A helper method which draws a line with the passed *painter*, according to the pixel data in *lineData*. NaN points create gaps in the line, as expected from QCustomPlot's plottables (this is the main difference to QPainter's regular drawPolyline, which handles NaNs by lagging or crashing).
Further it uses a faster line drawing technique based on QCPPainter::drawLine rather than `QPainter::drawPolyline` if the configured QCustomPlot::setPlottingHints() and *painter* style allows.

17.604.3.8 findBegin()

```
template<class DataType >
int QCPAbstractPlottable1D< DataType >::findBegin (
            double sortKey,
            bool expandedRange = true ) const  [virtual]
```

Returns the index of the data point with a (sort-)key that is equal to, just below, or just above *sortKey*. If *expandedRange* is true, the data point just below *sortKey* will be considered, otherwise the one just above.
This can be used in conjunction with findEnd to iterate over data points within a given key range, including or excluding the bounding data points that are just beyond the specified range.
If *expandedRange* is true but there are no data points below *sortKey*, 0 is returned.
If the container is empty, returns 0 (in that case, findEnd will also return 0, so a loop using these methods will not iterate over the index 0).

See also

findEnd, QCPDataContainer::findBegin

Implements QCPPlottableInterface1D.

17.604.3.9 findEnd()

```
template<class DataType >
int QCPAbstractPlottable1D< DataType >::findEnd (
            double sortKey,
            bool expandedRange = true ) const  [virtual]
```

Returns the index one after the data point with a (sort-)key that is equal to, just above, or just below *sortKey*. If *expandedRange* is true, the data point just above *sortKey* will be considered, otherwise the one just below.
This can be used in conjunction with findBegin to iterate over data points within a given key range, including the bounding data points that are just below and above the specified range.
If *expandedRange* is true but there are no data points above *sortKey*, the index just above the highest data point is returned.
If the container is empty, returns 0.

See also

findBegin, QCPDataContainer::findEnd

Implements QCPPlottableInterface1D.

17.604.3.10 getDataSegments()

```
template<class DataType >
void QCPAbstractPlottable1D< DataType >::getDataSegments (
            QList< QCPDataRange > & selectedSegments,
            QList< QCPDataRange > & unselectedSegments ) const  [protected]
```

Splits all data into selected and unselected segments and outputs them via *selectedSegments* and *unselected↩ Segments*, respectively.
This is useful when subclasses implement their draw method and need to draw selected segments with a different pen/brush than unselected segments (also see QCPSelectionDecorator).

See also

setSelection

17.604.3.11 interface1D()

```
template<class DataType >
QCPPlottableInterface1D * QCPAbstractPlottable1D< DataType >::interface1D ( )  [inline], [virtual]
```

Returns a QCPPlottableInterface1D pointer to this plottable, providing access to its 1D interface.
\seebaseclassmethod
Reimplemented from QCPAbstractPlottable.

17.604.3.12 selectTest()

```
template<class DataType >
double QCPAbstractPlottable1D< DataType >::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Implements a point-selection algorithm assuming the data (accessed via the 1D data interface) is point-like. Most subclasses will want to reimplement this method again, to provide a more accurate hit test based on the true data visualization geometry.
If *details* is not 0, it will be set to a QCPDataSelection, describing the closest data point to *pos*.
\seebaseclassmethod
Implements QCPAbstractPlottable.
Reimplemented in QCPGraph, QCPCurve, QCPBars, QCPStatisticalBox, and QCPFinancial.

17.604.3.13 selectTestRect()

```
template<class DataType >
QCPDataSelection QCPAbstractPlottable1D< DataType >::selectTestRect (
            const QRectF & rect,
            bool onlySelectable ) const  [virtual]
```

Implements a rect-selection algorithm assuming the data (accessed via the 1D data interface) is point-like. Most subclasses will want to reimplement this method again, to provide a more accurate hit test based on the true data visualization geometry.
\seebaseclassmethod
Implements QCPPlottableInterface1D.
Reimplemented in QCPBars, QCPStatisticalBox, and QCPFinancial.

17.604.3.14 sortKeyIsMainKey()

```
template<class DataType >
bool QCPAbstractPlottable1D< DataType >::sortKeyIsMainKey ( ) const  [virtual]
```

Returns whether the sort key (dataSortKey) is identical to the main key (dataMainKey).
What the sort and main keys are, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implements QCPPlottableInterface1D.

17.605.1 Detailed Description

Manages a single axis inside a QCustomPlot.
Usually doesn't need to be instantiated externally. Access QCustomPlot's default four axes via QCustomPlot::xAxis (bottom), QCustomPlot::yAxis (left), QCustomPlot::xAxis2 (top) and QCustomPlot::yAxis2 (right).
Axes are always part of an axis rect, see QCPAxisRect.

Naming convention of axis parts

Overview of the spacings and paddings that define the geometry of an axis. The dashed gray line on the left represents the QCustomPlot widget border.

Each axis holds an instance of QCPAxisTicker which is used to generate the tick coordinates and tick labels. You can access the currently installed ticker or set a new one (possibly one of the specialized subclasses, or your own subclass) via setTicker. For details, see the documentation of QCPAxisTicker.

17.605.2 Member Enumeration Documentation

17.605.2.1 AxisType

`enum QCPAxis::AxisType`
Defines at which side of the axis rect the axis will appear. This also affects how the tick marks are drawn, on which side the labels are placed etc.

Enumerator

atLeft	`0x01` Axis is vertical and on the left side of the axis rect
atRight	`0x02` Axis is vertical and on the right side of the axis rect
atTop	`0x04` Axis is horizontal and on the top side of the axis rect
atBottom	`0x08` Axis is horizontal and on the bottom side of the axis rect

17.605.2.2 LabelSide

`enum QCPAxis::LabelSide`
Defines on which side of the axis the tick labels (numbers) shall appear.

See also

setTickLabelSide

Enumerator

lsInside	Tick labels will be displayed inside the axis rect and clipped to the inner axis rect.
lsOutside	Tick labels will be displayed outside the axis rect.

17.605.2.3 ScaleType

`enum QCPAxis::ScaleType`
Defines the scale of an axis.

See also

setScaleType

Enumerator

stLinear	Linear scaling.
stLogarithmic	Logarithmic scaling with correspondingly transformed axis coordinates (possibly also setTicker to a QCPAxisTickerLog instance).

17.605.2.4 SelectablePart

```
enum QCPAxis::SelectablePart
```

Defines the selectable parts of an axis.

See also

setSelectableParts, setSelectedParts

Enumerator

spNone	None of the selectable parts.
spAxis	The axis backbone and tick marks.
spTickLabels	Tick labels (numbers) of this axis (as a whole, not individually)
spAxisLabel	The axis label.

17.605.3 Constructor & Destructor Documentation

17.605.3.1 QCPAxis()

```
QCPAxis::QCPAxis (
            QCPAxisRect * parent,
            AxisType type )  [explicit]
```

Constructs an Axis instance of Type *type* for the axis rect *parent*.
Usually it isn't necessary to instantiate axes directly, because you can let QCustomPlot create them for you with QCPAxisRect::addAxis. If you want to use own QCPAxis-subclasses however, create them manually and then inject them also via QCPAxisRect::addAxis.

17.605.4 Member Function Documentation

17.605.4.1 applyDefaultAntialiasingHint()

```
void QCPAxis::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Implements QCPLayerable.

17.605.4.2 coordToPixel()

```
double QCPAxis::coordToPixel (
            double value ) const
```

Transforms *value*, in coordinates of the axis, to pixel coordinates of the QCustomPlot widget.

17.605.4.3 deselectEvent()

```
void QCPAxis::deselectEvent (
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.605.4.4 draw()

```
void QCPAxis::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPLayerable.

17.605.4.5 getPartAt()

```
QCPAxis::SelectablePart QCPAxis::getPartAt (
            const QPointF & pos ) const
```

Returns the part of the axis that is hit by *pos* (in pixels). The return value of this function is independent of the user-selectable parts defined with setSelectableParts. Further, this function does not change the current selection state of the axis.
If the axis is not visible (setVisible), this function always returns spNone.

See also

setSelectedParts, setSelectableParts, QCustomPlot::setInteractions

17.605.4.6 graphs()

```
QList< QCPGraph * > QCPAxis::graphs ( ) const
```

Returns a list of all the graphs that have this axis as key or value axis.

See also

plottables, items

17.605.4.7 grid()

```
QCPGrid * QCPAxis::grid ( ) const  [inline]
```

Returns the QCPGrid instance belonging to this axis. Access it to set details about the way the grid is displayed.

17.605.4.8 items()

```
QList< QCPAbstractItem * > QCPAxis::items ( ) const
```

Returns a list of all the items that are associated with this axis. An item is considered associated with an axis if at least one of its positions uses the axis as key or value axis.

See also

plottables, graphs

17.605.4.9 marginSideToAxisType()

```
QCPAxis::AxisType QCPAxis::marginSideToAxisType (
            QCP::MarginSide side )  [static]
```

Transforms a margin side to the logically corresponding axis type. (QCP::msLeft to QCPAxis::atLeft, QCP::msRight to QCPAxis::atRight, etc.)

17.605.4.10 mouseMoveEvent()

```
void QCPAxis::mouseMoveEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user moves the mouse while holding a mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.605.4.11 mousePressEvent()

```
void QCPAxis::mousePressEvent (
            QMouseEvent * event,
            const QVariant & details )  [protected], [virtual]
```

This event gets called when the user presses a mouse button while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *details* contains layerable-specific details about the hit, which were generated in the previous call to selectTest. For example, One-dimensional plottables like QCPGraph or QCPBars convey the clicked data point in the *details* parameter, as QCPDataSelection packed as QVariant. Multi-part objects convey the specific `SelectablePart` that was hit (e.g. QCPAxis::SelectablePart in the case of axes).
QCustomPlot uses an event propagation system that works the same as Qt's system. If your layerable doesn't reimplement the mousePressEvent or explicitly calls `event->ignore()` in its reimplementation, the event will be propagated to the next layerable in the stacking order.
Once a layerable has accepted the mousePressEvent, it is considered the mouse grabber and will receive all following calls to mouseMoveEvent or mouseReleaseEvent for this mouse interaction (a "mouse interaction" in this context ends with the release).
The default implementation does nothing except explicitly ignoring the event with `event->ignore()`.

See also

mouseMoveEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.605.4.12 mouseReleaseEvent()

```
void QCPAxis::mouseReleaseEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user releases the mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseMoveEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.605.4.13 moveRange()

```
void QCPAxis::moveRange (
            double diff )
```

If the scale type (setScaleType) is stLinear, *diff* is added to the lower and upper bounds of the range. The range is simply moved by *diff*.
If the scale type is stLogarithmic, the range bounds are multiplied by *diff*. This corresponds to an apparent "linear" move in logarithmic scaling by a distance of log(diff).

17.605.4.14 opposite()

```
QCPAxis::AxisType QCPAxis::opposite (
            QCPAxis::AxisType type )  [static]
```

Returns the axis type that describes the opposite axis of an axis with the specified *type*.

17.605.4.15 orientation() [1/2]

```
Qt::Orientation QCPAxis::orientation ( ) const  [inline]
```
Returns the orientation of this axis. The axis orientation (horizontal or vertical) is deduced from the axis type (left, top, right or bottom).

See also

orientation(AxisType type), pixelOrientation

17.605.4.16 orientation() [2/2]

```
static Qt::Orientation QCPAxis::orientation (
            AxisType type )  [inline], [static]
```
Returns the orientation of the specified axis type

See also

orientation(), pixelOrientation

17.605.4.17 pixelOrientation()

```
int QCPAxis::pixelOrientation ( ) const  [inline]
```
Returns which direction points towards higher coordinate values/keys, in pixel space.
This method returns either 1 or -1. If it returns 1, then going in the positive direction along the orientation of the axis in pixels corresponds to going from lower to higher axis coordinates. On the other hand, if this method returns -1, going to smaller pixel values corresponds to going from lower to higher axis coordinates.
For example, this is useful to easily shift axis coordinates by a certain amount given in pixels, without having to care about reversed or vertically aligned axes:
```
double newKey = keyAxis->pixelToCoord(keyAxis->coordToPixel(oldKey)+10*keyAxis->pixelOrientation());
```
newKey will then contain a key that is ten pixels towards higher keys, starting from *oldKey*.

17.605.4.18 pixelToCoord()

```
double QCPAxis::pixelToCoord (
            double value ) const
```
Transforms *value*, in pixel coordinates of the QCustomPlot widget, to axis coordinates.

17.605.4.19 plottables()

```
QList< QCPAbstractPlottable * > QCPAxis::plottables ( ) const
```
Returns a list of all the plottables that have this axis as key or value axis.
If you are only interested in plottables of type QCPGraph, see graphs.

See also

graphs, items

17.605.4.20 rangeChanged [1/2]

```
void QCPAxis::rangeChanged (
            const QCPRange & newRange )  [signal]
```
This signal is emitted when the range of this axis has changed. You can connect it to the setRange slot of another axis to communicate the new range to the other axis, in order for it to be synchronized.
You may also manipulate/correct the range with setRange in a slot connected to this signal. This is useful if for example a maximum range span shall not be exceeded, or if the lower/upper range shouldn't go beyond certain values (see QCPRange::bounded). For example, the following slot would limit the x axis to ranges between 0 and 10:
```
customPlot->xAxis->setRange(newRange.bounded(0, 10))
```

17.605.4.21 rangeChanged [2/2]

```
void QCPAxis::rangeChanged (
            const QCPRange & newRange,
            const QCPRange & oldRange )  [signal]
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Additionally to the new range, this signal also provides the previous range held by the axis as *oldRange*.

17.605.4.22 rescale()

```
void QCPAxis::rescale (
            bool onlyVisiblePlottables = false )
```

Changes the axis range such that all plottables associated with this axis are fully visible in that dimension.

See also

QCPAbstractPlottable::rescaleAxes, QCustomPlot::rescaleAxes

17.605.4.23 scaleRange() [1/2]

```
void QCPAxis::scaleRange (
            double factor )
```

Scales the range of this axis by *factor* around the center of the current axis range. For example, if *factor* is 2.0, then the axis range will double its size, and the point at the axis range center won't have changed its position in the QCustomPlot widget (i.e. coordinates around the center will have moved symmetrically closer).
If you wish to scale around a different coordinate than the current axis range center, use the overload scaleRange(double factor, double center).

17.605.4.24 scaleRange() [2/2]

```
void QCPAxis::scaleRange (
            double factor,
            double center )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Scales the range of this axis by *factor* around the coordinate *center*. For example, if *factor* is 2.0, *center* is 1.0, then the axis range will double its size, and the point at coordinate 1.0 won't have changed its position in the QCustomPlot widget (i.e. coordinates around 1.0 will have moved symmetrically closer to 1.0).

See also

scaleRange(double factor)

17.605.4.25 scaleTypeChanged

```
void QCPAxis::scaleTypeChanged (
            QCPAxis::ScaleType scaleType )  [signal]
```

This signal is emitted when the scale type changes, by calls to setScaleType

17.605.4.26 selectableChanged

```
void QCPAxis::selectableChanged (
            const QCPAxis::SelectableParts & parts )  [signal]
```

This signal is emitted when the selectability changes, by calls to setSelectableParts

17.605.4.27 selectEvent()

```
void QCPAxis::selectEvent (
            QMouseEvent * event,
            bool additive,
            const QVariant & details,
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.605.4.28 selectionCategory()

```
QCP::Interaction QCPAxis::selectionCategory ( ) const  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.605.4.29 selectionChanged

```
void QCPAxis::selectionChanged (
            const QCPAxis::SelectableParts & parts )  [signal]
```

This signal is emitted when the selection state of this axis has changed, either by user interaction or by a direct call to setSelectedParts.

17.605.4.30 selectTest()

```
double QCPAxis::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

See also

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Reimplemented from QCPLayerable.

17.605.4.31 setBasePen()

```
void QCPAxis::setBasePen (
            const QPen & pen )
```

Sets the pen, the axis base line is drawn with.

See also

setTickPen, setSubTickPen

17.605.4.32 setLabel()

```
void QCPAxis::setLabel (
            const QString & str )
```

Sets the text of the axis label that will be shown below/above or next to the axis, depending on its orientation. To disable axis labels, pass an empty string as *str*.

17.605.4.33 setLabelColor()

```
void QCPAxis::setLabelColor (
            const QColor & color )
```

Sets the color of the axis label.

See also

setLabelFont

17.605.4.34 setLabelFont()

```
void QCPAxis::setLabelFont (
            const QFont & font )
```

Sets the font of the axis label.

See also

setLabelColor

17.605.4.35 setLabelPadding()

```
void QCPAxis::setLabelPadding (
            int padding )
```

Sets the distance between the tick labels and the axis label.

See also

setTickLabelPadding, setPadding

17.605.4.36 setLowerEnding()

```
void QCPAxis::setLowerEnding (
            const QCPLineEnding & ending )
```

Sets the style for the lower axis ending. See the documentation of QCPLineEnding for available styles.
For horizontal axes, this method refers to the left ending, for vertical axes the bottom ending. Note that this meaning does not change when the axis range is reversed with setRangeReversed.

See also

setUpperEnding

17.605.4.37 setNumberFormat()

```
void QCPAxis::setNumberFormat (
            const QString & formatCode )
```

Sets the number format for the numbers in tick labels. This *formatCode* is an extended version of the format code used e.g. by QString::number() and QLocale::toString(). For reference about that, see the "Argument Formats" section in the detailed description of the QString class.

formatCode is a string of one, two or three characters.
The first character is identical to the normal format code used by Qt. In short, this means: 'e'/'E' scientific format, 'f' fixed format, 'g'/'G' scientific or fixed, whichever is shorter. For the 'e', 'E', and 'f' formats, the precision set by setNumberPrecision represents the number of digits after the decimal point. For the 'g' and 'G' formats, the precision represents the maximum number of significant digits, trailing zeroes are omitted.
The second and third characters are optional and specific to QCustomPlot:
If the first char was 'e' or 'g', numbers are/might be displayed in the scientific format, e.g. "5.5e9", which is ugly in a plot. So when the second char of *formatCode* is set to 'b' (for "beautiful"), those exponential numbers are formatted in a more natural way, i.e. "5.5 [multiplication sign] 10 [superscript] 9". By default, the multiplication sign is a centered dot. If instead a cross should be shown (as is usual in the USA), the third char of *formatCode* can be set to 'c'. The inserted multiplication signs are the UTF-8 characters 215 (0xD7) for the cross and 183 (0xB7) for the dot.
Examples for *formatCode:*

- `g` normal format code behaviour. If number is small, fixed format is used, if number is large, normal scientific format is used
- `gb` If number is small, fixed format is used, if number is large, scientific format is used with beautifully typeset decimal powers and a dot as multiplication sign
- `ebc` All numbers are in scientific format with beautifully typeset decimal power and a cross as multiplication sign
- `fb` illegal format code, since fixed format doesn't support (or need) beautifully typeset decimal powers. Format code will be reduced to 'f'.
- `hello` illegal format code, since first char is not 'e', 'E', 'f', 'g' or 'G'. Current format code will not be changed.

17.605.4.38 setNumberPrecision()

```
void QCPAxis::setNumberPrecision (
            int precision )
```

Sets the precision of the tick label numbers. See QLocale::toString(double i, char f, int prec) for details. The effect of precisions are most notably for number Formats starting with 'e', see setNumberFormat

17.605.4.39 setOffset()

```
void QCPAxis::setOffset (
            int offset )
```

Sets the offset the axis has to its axis rect side.
If an axis rect side has multiple axes and automatic margin calculation is enabled for that side, only the offset of the inner most axis has meaning (even if it is set to be invisible). The offset of the other, outer axes is controlled automatically, to place them at appropriate positions.

17.605.4.40 setPadding()

```
void QCPAxis::setPadding (
            int padding )
```

Sets the padding of the axis.
When QCPAxisRect::setAutoMargins is enabled, the padding is the additional outer most space, that is left blank.
The axis padding has no meaning if QCPAxisRect::setAutoMargins is disabled.

See also

setLabelPadding, setTickLabelPadding

17.605.4.41 setRange() [1/3]

```
void QCPAxis::setRange (
            const QCPRange & range )
```

Sets the range of the axis.
This slot may be connected with the rangeChanged signal of another axis so this axis is always synchronized with the other axis range, when it changes.
To invert the direction of an axis, use setRangeReversed.

17.605.4.42 setRange() [2/3]

```
void QCPAxis::setRange (
            double lower,
            double upper )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the lower and upper bound of the axis range.
To invert the direction of an axis, use setRangeReversed.
There is also a slot to set a range, see setRange(const QCPRange &range).

17.605.4.43 setRange() [3/3]

```
void QCPAxis::setRange (
            double position,
            double size,
            Qt::AlignmentFlag alignment )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the range of the axis.
The *position* coordinate indicates together with the *alignment* parameter, where the new range will be positioned. *size* defines the size of the new axis range. *alignment* may be Qt::AlignLeft, Qt::AlignRight or Qt::AlignCenter. This will cause the left border, right border, or center of the range to be aligned with *position*. Any other values of *alignment* will default to Qt::AlignCenter.

17.605.4.44 setRangeLower()

```
void QCPAxis::setRangeLower (
            double lower )
```

Sets the lower bound of the axis range. The upper bound is not changed.

See also

setRange

17.605.4.45 setRangeReversed()

```
void QCPAxis::setRangeReversed (
            bool reversed )
```

Sets whether the axis range (direction) is displayed reversed. Normally, the values on horizontal axes increase left to right, on vertical axes bottom to top. When *reversed* is set to true, the direction of increasing values is inverted.
Note that the range and data interface stays the same for reversed axes, e.g. the *lower* part of the setRange interface will still reference the mathematically smaller number than the *upper* part.

17.605.4.46 setRangeUpper()

```
void QCPAxis::setRangeUpper (
            double upper )
```

Sets the upper bound of the axis range. The lower bound is not changed.

See also

setRange

17.605.4.47 setScaleRatio()

```
void QCPAxis::setScaleRatio (
            const QCPAxis * otherAxis,
            double ratio = 1.0 )
```

Scales the range of this axis to have a certain scale *ratio* to *otherAxis*. The scaling will be done around the center of the current axis range.
For example, if *ratio* is 1, this axis is the *yAxis* and *otherAxis* is *xAxis*, graphs plotted with those axes will appear in a 1:1 aspect ratio, independent of the aspect ratio the axis rect has.
This is an operation that changes the range of this axis once, it doesn't fix the scale ratio indefinitely. Note that calling this function in the constructor of the QCustomPlot's parent won't have the desired effect, since the widget dimensions aren't defined yet, and a resizeEvent will follow.

17.605.4.48 setScaleType()

```
void QCPAxis::setScaleType (
            QCPAxis::ScaleType type )
```

Sets whether the axis uses a linear scale or a logarithmic scale.
Note that this method controls the coordinate transformation. For logarithmic scales, you will likely also want to use a logarithmic tick spacing and labeling, which can be achieved by setting the axis ticker to an instance of QCPAxisTickerLog :
See the documentation of QCPAxisTickerLog about the details of logarithmic axis tick creation.
setNumberPrecision

17.605.4.49 setSelectableParts()

```
void QCPAxis::setSelectableParts (
            const QCPAxis::SelectableParts & selectableParts )
```

Sets whether the user can (de-)select the parts in *selectable* by clicking on the QCustomPlot surface. (When QCustomPlot::setInteractions contains iSelectAxes.)
However, even when *selectable* is set to a value not allowing the selection of a specific part, it is still possible to set the selection of this part manually, by calling setSelectedParts directly.

See also

SelectablePart, setSelectedParts

17.605.4.50 setSelectedBasePen()

```
void QCPAxis::setSelectedBasePen (
            const QPen & pen )
```

Sets the pen that is used to draw the axis base line when selected.

See also

setBasePen, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.605.4.51 setSelectedLabelColor()

```
void QCPAxis::setSelectedLabelColor (
            const QColor & color )
```

Sets the color that is used for the axis label when it is selected.

See also

setLabelColor, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.605.4.52 setSelectedLabelFont()

```
void QCPAxis::setSelectedLabelFont (
            const QFont & font )
```

Sets the font that is used for the axis label when it is selected.

See also

setLabelFont, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.605.4.53 setSelectedParts()

```
void QCPAxis::setSelectedParts (
            const QCPAxis::SelectableParts & selectedParts )
```

Sets the selected state of the respective axis parts described by SelectablePart. When a part is selected, it uses a different pen/font.
The entire selection mechanism for axes is handled automatically when QCustomPlot::setInteractions contains iSelectAxes. You only need to call this function when you wish to change the selection state manually.
This function can change the selection state of a part, independent of the setSelectableParts setting.
emits the selectionChanged signal when *selected* is different from the previous selection state.

See also

SelectablePart, setSelectableParts, selectTest, setSelectedBasePen, setSelectedTickPen, setSelectedSubTickPen, setSelectedTickLabelFont, setSelectedLabelFont, setSelectedTickLabelColor, setSelectedLabelColor

17.605.4.54 setSelectedSubTickPen()

```
void QCPAxis::setSelectedSubTickPen (
            const QPen & pen )
```

Sets the pen that is used to draw the subticks when selected.

See also

setSubTickPen, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.605.4.55 setSelectedTickLabelColor()

```
void QCPAxis::setSelectedTickLabelColor (
            const QColor & color )
```

Sets the color that is used for tick labels when they are selected.

See also

setTickLabelColor, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.605.4.56 setSelectedTickLabelFont()

```
void QCPAxis::setSelectedTickLabelFont (
            const QFont & font )
```

Sets the font that is used for tick labels when they are selected.

See also

setTickLabelFont, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.605.4.57 setSelectedTickPen()

```
void QCPAxis::setSelectedTickPen (
            const QPen & pen )
```

Sets the pen that is used to draw the (major) ticks when selected.

See also

setTickPen, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.605.4.58 setSubTickLength()

```
void QCPAxis::setSubTickLength (
            int inside,
            int outside = 0 )
```

Sets the length of the subticks in pixels. *inside* is the length the subticks will reach inside the plot and *outside* is the length they will reach outside the plot. If *outside* is greater than zero, the tick labels and axis label will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setTickLength, setSubTickLengthIn, setSubTickLengthOut

17.605.4.59 setSubTickLengthIn()

```
void QCPAxis::setSubTickLengthIn (
            int inside )
```

Sets the length of the inward subticks in pixels. *inside* is the length the subticks will reach inside the plot.

See also

setSubTickLengthOut, setSubTickLength, setTickLength

17.605.4.60 setSubTickLengthOut()

```
void QCPAxis::setSubTickLengthOut (
            int outside )
```

Sets the length of the outward subticks in pixels. *outside* is the length the subticks will reach outside the plot. If *outside* is greater than zero, the tick labels will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setSubTickLengthIn, setSubTickLength, setTickLength

17.605.4.61 setSubTickPen()

```
void QCPAxis::setSubTickPen (
            const QPen & pen )
```

Sets the pen, subtick marks will be drawn with.

See also

setSubTickCount, setSubTickLength, setBasePen

17.605.4.62 setSubTicks()

```
void QCPAxis::setSubTicks (
            bool show )
```

Sets whether sub tick marks are displayed.
Sub ticks are only potentially visible if (major) ticks are also visible (see setTicks)

See also

setTicks

17.605.4.63 setTicker()

```
void QCPAxis::setTicker (
            QSharedPointer< QCPAxisTicker > ticker )
```

The axis ticker is responsible for generating the tick positions and tick labels. See the documentation of QCPAxisTicker for details on how to work with axis tickers.
You can change the tick positioning/labeling behaviour of this axis by setting a different QCPAxisTicker subclass using this method. If you only wish to modify the currently installed axis ticker, access it via ticker.
Since the ticker is stored in the axis as a shared pointer, multiple axes may share the same axis ticker simply by passing the same shared pointer to multiple axes.

See also

ticker

17.605.4.64 setTickLabelColor()

```
void QCPAxis::setTickLabelColor (
            const QColor & color )
```

Sets the color of the tick labels.

See also

setTickLabels, setTickLabelFont

17.605.4.65 setTickLabelFont()

```
void QCPAxis::setTickLabelFont (
            const QFont & font )
```

Sets the font of the tick labels.

See also

setTickLabels, setTickLabelColor

17.605.4.66 setTickLabelPadding()

```
void QCPAxis::setTickLabelPadding (
            int padding )
```

Sets the distance between the axis base line (including any outward ticks) and the tick labels.

See also

setLabelPadding, setPadding

17.605.4.67 setTickLabelRotation()

```
void QCPAxis::setTickLabelRotation (
            double degrees )
```

Sets the rotation of the tick labels. If *degrees* is zero, the labels are drawn normally. Else, the tick labels are drawn rotated by *degrees* clockwise. The specified angle is bound to values from -90 to 90 degrees.
If *degrees* is exactly -90, 0 or 90, the tick labels are centered on the tick coordinate. For other angles, the label is drawn with an offset such that it seems to point toward or away from the tick mark.

17.605.4.68 setTickLabels()

```
void QCPAxis::setTickLabels (
            bool show )
```

Sets whether tick labels are displayed. Tick labels are the numbers drawn next to tick marks.

17.605.4.69 setTickLabelSide()

```
void QCPAxis::setTickLabelSide (
            LabelSide side )
```

Sets whether the tick labels (numbers) shall appear inside or outside the axis rect.
The usual and default setting is lsOutside. Very compact plots sometimes require tick labels to be inside the axis rect, to save space. If *side* is set to lsInside, the tick labels appear on the inside are additionally clipped to the axis rect.

17.605.4.70 setTickLength()

```
void QCPAxis::setTickLength (
            int inside,
            int outside = 0 )
```

Sets the length of the ticks in pixels. *inside* is the length the ticks will reach inside the plot and *outside* is the length they will reach outside the plot. If *outside* is greater than zero, the tick labels and axis label will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setSubTickLength, setTickLengthIn, setTickLengthOut

17.605.4.71 setTickLengthIn()

```
void QCPAxis::setTickLengthIn (
            int inside )
```

Sets the length of the inward ticks in pixels. *inside* is the length the ticks will reach inside the plot.

See also

setTickLengthOut, setTickLength, setSubTickLength

17.605.4.72 setTickLengthOut()

```
void QCPAxis::setTickLengthOut (
            int outside )
```

Sets the length of the outward ticks in pixels. *outside* is the length the ticks will reach outside the plot. If *outside* is greater than zero, the tick labels and axis label will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setTickLengthIn, setTickLength, setSubTickLength

17.605.4.73 setTickPen()

```
void QCPAxis::setTickPen (
            const QPen & pen )
```

Sets the pen, tick marks will be drawn with.

See also

setTickLength, setBasePen

17.605.4.74 setTicks()

```
void QCPAxis::setTicks (
            bool show )
```

Sets whether tick marks are displayed.
Note that setting *show* to false does not imply that tick labels are invisible, too. To achieve that, see setTickLabels.

See also

setSubTicks

17.605.4.75 setUpperEnding()

```
void QCPAxis::setUpperEnding (
            const QCPLineEnding & ending )
```

Sets the style for the upper axis ending. See the documentation of QCPLineEnding for available styles.
For horizontal axes, this method refers to the right ending, for vertical axes the top ending. Note that this meaning does not change when the axis range is reversed with setRangeReversed.

See also

setLowerEnding

17.605.4.76 ticker()

```
QSharedPointer< QCPAxisTicker > QCPAxis::ticker ( ) const  [inline]
```

Returns a modifiable shared pointer to the currently installed axis ticker. The axis ticker is responsible for generating the tick positions and tick labels of this axis. You can access the QCPAxisTicker with this method and modify basic properties such as the approximate tick count (QCPAxisTicker::setTickCount).
You can gain more control over the axis ticks by setting a different QCPAxisTicker subclass, see the documentation there. A new axis ticker can be set with setTicker.
Since the ticker is stored in the axis as a shared pointer, multiple axes may share the same axis ticker simply by passing the same shared pointer to multiple axes.

See also

setTicker

17.605.4.77 wheelEvent()

```
void QCPAxis::wheelEvent (
            QWheelEvent * event )  [protected], [virtual]
```

This event gets called when the user turns the mouse scroll wheel while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`.
The `event->angleDelta()` indicates how far the mouse wheel was turned, which is usually +/- 120 for single rotation steps. However, if the mouse wheel is turned rapidly, multiple steps may accumulate to one event, making the delta larger. On the other hand, if the wheel has very smooth steps or none at all, the delta may be smaller.
The default implementation does nothing.

17.607.1 Detailed Description

Holds multiple axes and arranges them in a rectangular shape.
This class represents an axis rect, a rectangular area that is bounded on all sides with an arbitrary number of axes. Initially QCustomPlot has one axis rect, accessible via QCustomPlot::axisRect(). However, the layout system allows to have multiple axis rects, e.g. arranged in a grid layout (QCustomPlot::plotLayout).
By default, QCPAxisRect comes with four axes, at bottom, top, left and right. They can be accessed via axis by providing the respective axis type (QCPAxis::AxisType) and index. If you need all axes in the axis rect, use axes. The top and right axes are set to be invisible initially (QCPAxis::setVisible). To add more axes to a side, use addAxis or addAxes. To remove an axis, use removeAxis.
The axis rect layerable itself only draws a background pixmap or color, if specified (setBackground). It is placed on the "background" layer initially (see QCPLayer for an explanation of the QCustomPlot layer system). The axes that are held by the axis rect can be placed on other layers, independently of the axis rect.
Every axis rect has a child layout of type QCPLayoutInset. It is accessible via insetLayout and can be used to have other layout elements (or even other layouts with multiple elements) hovering inside the axis rect.
If an axis rect is clicked and dragged, it processes this by moving certain axis ranges. The behaviour can be controlled with setRangeDrag and setRangeDragAxes. If the mouse wheel is scrolled while the cursor is on the axis rect, certain axes are scaled. This is controllable via setRangeZoom, setRangeZoomAxes and setRangeZoomFactor. These interactions are only enabled if QCustomPlot::setInteractions contains QCP::iRangeDrag and QCP::iRangeZoom.

Overview of the spacings and paddings that define the geometry of an axis. The dashed line on the far left indicates the viewport/widget border.

17.607.2 Constructor & Destructor Documentation

17.607.2.1 QCPAxisRect()

```
QCPAxisRect::QCPAxisRect (
            QCustomPlot * parentPlot,
            bool setupDefaultAxes = true )  [explicit]
```

Creates a QCPAxisRect instance and sets default values. An axis is added for each of the four sides, the top and right axes are set invisible initially.

17.607.3 Member Function Documentation

17.607.3.1 addAxes()

```
QList< QCPAxis * > QCPAxisRect::addAxes (
            QCPAxis::AxisTypes types )
```

Adds a new axis with addAxis to each axis rect side specified in *types*. This may be an `or`-combination of QCPAxis::AxisType, so axes can be added to multiple sides at once.
Returns a list of the added axes.

See also

addAxis, setupFullAxesBox

17.607.3.2 addAxis()

```
QCPAxis * QCPAxisRect::addAxis (
            QCPAxis::AxisType type,
            QCPAxis * axis = nullptr )
```

Adds a new axis to the axis rect side specified with *type*, and returns it. If *axis* is 0, a new QCPAxis instance is created internally. QCustomPlot owns the returned axis, so if you want to remove an axis, use removeAxis instead of deleting it manually.
You may inject QCPAxis instances (or subclasses of QCPAxis) by setting *axis* to an axis that was previously created outside QCustomPlot. It is important to note that QCustomPlot takes ownership of the axis, so you may not delete it afterwards. Further, the *axis* must have been created with this axis rect as parent and with the same axis type as specified in *type*. If this is not the case, a debug output is generated, the axis is not added, and the method returns `nullptr`.
This method can not be used to move *axis* between axis rects. The same *axis* instance must not be added multiple times to the same or different axis rects.
If an axis rect side already contains one or more axes, the lower and upper endings of the new axis (QCPAxis::setLowerEnding, QCPAxis::setUpperEnding) are set to QCPLineEnding::esHalfBar.

See also

addAxes, setupFullAxesBox

17.607.3.3 applyDefaultAntialiasingHint()

```
void QCPAxisRect::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Reimplemented from QCPLayoutElement.

17.607.3.4 axes() [1/2]

```
QList< QCPAxis * > QCPAxisRect::axes ( ) const
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Returns all axes of this axis rect.

17.607.3.5 axes() [2/2]

```
QList< QCPAxis * > QCPAxisRect::axes (
            QCPAxis::AxisTypes types ) const
```

Returns all axes on the axis rect sides specified with *types*.
types may be a single QCPAxis::AxisType or an `or`-combination, to get the axes of multiple sides.

See also

axis

17.607.3.6 axis()

```
QCPAxis * QCPAxisRect::axis (
            QCPAxis::AxisType type,
            int index = 0 ) const
```

Returns the axis with the given *index* on the axis rect side specified with *type*.

See also

axisCount, axes

17.607.3.7 axisCount()

```
int QCPAxisRect::axisCount (
            QCPAxis::AxisType type ) const
```

Returns the number of axes on the axis rect side specified with *type*.

See also

axis

17.607.3.8 bottom()

```
int QCPAxisRect::bottom ( ) const  [inline]
```

Returns the pixel position of the bottom border of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.9 bottomLeft()

```
QPoint QCPAxisRect::bottomLeft ( ) const  [inline]
```

Returns the bottom left corner of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.10 bottomRight()

```
QPoint QCPAxisRect::bottomRight ( ) const  [inline]
```

Returns the bottom right corner of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.11 calculateAutoMargin()

```
int QCPAxisRect::calculateAutoMargin (
            QCP::MarginSide side )  [protected], [virtual]
```

Reimplemented from QCPLayoutElement.

17.607.3.12 center()

```
QPoint QCPAxisRect::center ( ) const  [inline]
```

Returns the center of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.13 draw()

```
void QCPAxisRect::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Reimplemented from QCPLayoutElement.

17.607.3.14 elements()

```
QList< QCPLayoutElement * > QCPAxisRect::elements (
            bool recursive ) const  [virtual]
```

Returns a list of all child elements in this layout element. If *recursive* is true, all sub-child elements are included in the list, too.

Warning

There may be `nullptr` entries in the returned list. For example, QCPLayoutGrid may have empty cells which yield `nullptr` at the respective index.

Reimplemented from QCPLayoutElement.

17.607.3.15 graphs()

```
QList< QCPGraph * > QCPAxisRect::graphs ( ) const
```

Returns a list of all the graphs that are associated with this axis rect.
A graph is considered associated with an axis rect if its key or value axis (or both) is in this axis rect.

See also

plottables, items

17.607.3.16 height()

```
int QCPAxisRect::height ( ) const  [inline]
```

Returns the pixel height of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.17 insetLayout()

```
QCPLayoutInset * QCPAxisRect::insetLayout ( ) const  [inline]
```

Returns the inset layout of this axis rect. It can be used to place other layout elements (or even layouts with multiple other elements) inside/on top of an axis rect.

See also

QCPLayoutInset

17.607.3.18 items()

```
QList< QCPAbstractItem * > QCPAxisRect::items ( ) const
```

Returns a list of all the items that are associated with this axis rect.
An item is considered associated with an axis rect if any of its positions has key or value axis set to an axis that is in this axis rect, or if any of its positions has QCPItemPosition::setAxisRect set to the axis rect, or if the clip axis rect (QCPAbstractItem::setClipAxisRect) is set to this axis rect.

See also

plottables, graphs

17.607.3.19 layoutChanged()

```
void QCPAxisRect::layoutChanged ( )  [protected], [virtual]
```

Reimplemented from QCPLayoutElement.

17.607.3.20 left()

```
int QCPAxisRect::left ( ) const  [inline]
```

Returns the pixel position of the left border of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.21 mouseMoveEvent()

```
void QCPAxisRect::mouseMoveEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user moves the mouse while holding a mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.
Reimplemented in QCPColorScaleAxisRectPrivate.

17.607.3.22 mousePressEvent()

```
void QCPAxisRect::mousePressEvent (
            QMouseEvent * event,
            const QVariant & details )  [protected], [virtual]
```

This event gets called when the user presses a mouse button while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *details* contains layerable-specific details about the hit, which were generated in the previous call to selectTest. For example, One-dimensional plottables like QCPGraph or QCPBars convey the clicked data point in the *details* parameter, as QCPDataSelection packed as QVariant. Multi-part objects convey the specific `SelectablePart` that was hit (e.g. QCPAxis::SelectablePart in the case of axes).
QCustomPlot uses an event propagation system that works the same as Qt's system. If your layerable doesn't reimplement the mousePressEvent or explicitly calls `event->ignore()` in its reimplementation, the event will be propagated to the next layerable in the stacking order.
Once a layerable has accepted the mousePressEvent, it is considered the mouse grabber and will receive all following calls to mouseMoveEvent or mouseReleaseEvent for this mouse interaction (a "mouse interaction" in this context ends with the release).
The default implementation does nothing except explicitly ignoring the event with `event->ignore()`.

See also

mouseMoveEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.
Reimplemented in QCPColorScaleAxisRectPrivate.

17.607.3.23 mouseReleaseEvent()

```
void QCPAxisRect::mouseReleaseEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user releases the mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseMoveEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.
Reimplemented in QCPColorScaleAxisRectPrivate.

17.607.3.24 plottables()

```
QList< QCPAbstractPlottable * > QCPAxisRect::plottables ( ) const
```

Returns a list of all the plottables that are associated with this axis rect.
A plottable is considered associated with an axis rect if its key or value axis (or both) is in this axis rect.

See also

graphs, items

17.607.3.25 rangeDragAxes()

```
QList< QCPAxis * > QCPAxisRect::rangeDragAxes (
            Qt::Orientation orientation )
```

Returns all range drag axes of the *orientation* provided.

See also

rangeZoomAxis, setRangeZoomAxes

17.607.3.26 rangeDragAxis()

```
QCPAxis * QCPAxisRect::rangeDragAxis (
            Qt::Orientation orientation )
```

Returns the range drag axis of the *orientation* provided. If multiple axes were set, returns the first one (use rangeDragAxes to retrieve a list with all set axes).

See also

setRangeDragAxes

17.607.3.27 rangeZoomAxes()

```
QList< QCPAxis * > QCPAxisRect::rangeZoomAxes (
            Qt::Orientation orientation )
```

Returns all range zoom axes of the *orientation* provided.

See also

rangeDragAxis, setRangeDragAxes

17.607.3.28 rangeZoomAxis()

```
QCPAxis * QCPAxisRect::rangeZoomAxis (
            Qt::Orientation orientation )
```

Returns the range zoom axis of the *orientation* provided. If multiple axes were set, returns the first one (use rangeZoomAxes to retrieve a list with all set axes).

See also

setRangeZoomAxes

17.607.3.29 rangeZoomFactor()

```
double QCPAxisRect::rangeZoomFactor (
            Qt::Orientation orientation )
```

Returns the range zoom factor of the *orientation* provided.

See also

setRangeZoomFactor

17.607.3.30 removeAxis()

```
bool QCPAxisRect::removeAxis (
            QCPAxis * axis )
```

Removes the specified *axis* from the axis rect and deletes it.
Returns true on success, i.e. if *axis* was a valid axis in this axis rect.

See also

addAxis

17.607.3.31 right()

```
int QCPAxisRect::right ( ) const  [inline]
```

Returns the pixel position of the right border of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.32 setBackground() [1/3]

```
void QCPAxisRect::setBackground (
            const QBrush & brush )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets *brush* as the background brush. The axis rect background will be filled with this brush. Since axis rects place themselves on the "background" layer by default, the axis rect backgrounds are usually drawn below everything else.
The brush will be drawn before (under) any background pixmap, which may be specified with setBackground(const QPixmap &pm).
To disable drawing of a background brush, set *brush* to Qt::NoBrush.

See also

setBackground(const QPixmap &pm)

17.607.3.33 setBackground() [2/3]

```
void QCPAxisRect::setBackground (
            const QPixmap & pm )
```

Sets *pm* as the axis background pixmap. The axis background pixmap will be drawn inside the axis rect. Since axis rects place themselves on the "background" layer by default, the axis rect backgrounds are usually drawn below everything else.
For cases where the provided pixmap doesn't have the same size as the axis rect, scaling can be enabled with setBackgroundScaled and the scaling mode (i.e. whether and how the aspect ratio is preserved) can be set with setBackgroundScaledMode. To set all these options in one call, consider using the overloaded version of this function.
Below the pixmap, the axis rect may be optionally filled with a brush, if specified with setBackground(const QBrush &brush).

See also

setBackgroundScaled, setBackgroundScaledMode, setBackground(const QBrush &brush)

17.607.3.34 setBackground() [3/3]

```
void QCPAxisRect::setBackground (
            const QPixmap & pm,
            bool scaled,
            Qt::AspectRatioMode mode = Qt::KeepAspectRatioByExpanding )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Allows setting the background pixmap of the axis rect, whether it shall be scaled and how it shall be scaled in one call.

See also

setBackground(const QPixmap &pm), setBackgroundScaled, setBackgroundScaledMode

17.607.3.35 setBackgroundScaled()

```
void QCPAxisRect::setBackgroundScaled (
            bool scaled )
```

Sets whether the axis background pixmap shall be scaled to fit the axis rect or not. If *scaled* is set to true, you may control whether and how the aspect ratio of the original pixmap is preserved with setBackgroundScaledMode.
Note that the scaled version of the original pixmap is buffered, so there is no performance penalty on replots. (Except when the axis rect dimensions are changed continuously.)

See also

setBackground, setBackgroundScaledMode

17.607.3.36 setBackgroundScaledMode()

```
void QCPAxisRect::setBackgroundScaledMode (
            Qt::AspectRatioMode mode )
```

If scaling of the axis background pixmap is enabled (setBackgroundScaled), use this function to define whether and how the aspect ratio of the original pixmap passed to setBackground is preserved.

See also

setBackground, setBackgroundScaled

17.607.3.37 setRangeDrag()

```
void QCPAxisRect::setRangeDrag (
            Qt::Orientations orientations )
```

Sets which axis orientation may be range dragged by the user with mouse interaction. What orientation corresponds to which specific axis can be set with setRangeDragAxes(QCPAxis *horizontal, QCPAxis *vertical). By default, the horizontal axis is the bottom axis (xAxis) and the vertical axis is the left axis (yAxis).
To disable range dragging entirely, pass `nullptr` as *orientations* or remove QCP::iRangeDrag from QCustomPlot::setInteractions. To enable range dragging for both directions, pass `Qt::Horizontal | Qt::Vertical` as *orientations*.
In addition to setting *orientations* to a non-zero value, make sure QCustomPlot::setInteractions contains QCP::iRangeDrag to enable the range dragging interaction.

See also

setRangeZoom, setRangeDragAxes, QCustomPlot::setNoAntialiasingOnDrag

17.607.3.38 setRangeDragAxes() [1/3]

```
void QCPAxisRect::setRangeDragAxes (
            QCPAxis * horizontal,
            QCPAxis * vertical )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the axes whose range will be dragged when setRangeDrag enables mouse range dragging on the QCustomPlot widget. Pass `nullptr` if no axis shall be dragged in the respective orientation.
Use the overload taking a list of axes, if multiple axes (more than one per orientation) shall react to dragging interactions.

See also

setRangeZoomAxes

17.607.3.39 setRangeDragAxes() [2/3]

```
void QCPAxisRect::setRangeDragAxes (
            QList< QCPAxis * > axes )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
This method allows to set up multiple axes to react to horizontal and vertical dragging. The drag orientation that the respective axis will react to is deduced from its orientation (QCPAxis::orientation).
In the unusual case that you wish to e.g. drag a vertically oriented axis with a horizontal drag motion, use the overload taking two separate lists for horizontal and vertical dragging.

17.607.3.40 setRangeDragAxes() [3/3]

```
void QCPAxisRect::setRangeDragAxes (
            QList< QCPAxis * > horizontal,
            QList< QCPAxis * > vertical )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
This method allows to set multiple axes up to react to horizontal and vertical dragging, and define specifically which axis reacts to which drag orientation (irrespective of the axis orientation).

17.607.3.41 setRangeZoom()

```
void QCPAxisRect::setRangeZoom (
            Qt::Orientations orientations )
```

Sets which axis orientation may be zoomed by the user with the mouse wheel. What orientation corresponds to which specific axis can be set with setRangeZoomAxes(QCPAxis *horizontal, QCPAxis *vertical). By default, the horizontal axis is the bottom axis (xAxis) and the vertical axis is the left axis (yAxis).
To disable range zooming entirely, pass `nullptr` as *orientations* or remove QCP::iRangeZoom from QCustomPlot::setInteractions. To enable range zooming for both directions, pass `Qt::Horizontal | Qt::Vertical` as *orientations*.
In addition to setting *orientations* to a non-zero value, make sure QCustomPlot::setInteractions contains QCP::iRangeZoom to enable the range zooming interaction.

See also

setRangeZoomFactor, setRangeZoomAxes, setRangeDrag

17.607.3.42 setRangeZoomAxes() [1/3]

```
void QCPAxisRect::setRangeZoomAxes (
            QCPAxis * horizontal,
            QCPAxis * vertical )
```

Sets the axes whose range will be zoomed when setRangeZoom enables mouse wheel zooming on the QCustomPlot widget. Pass `nullptr` if no axis shall be zoomed in the respective orientation.
The two axes can be zoomed with different strengths, when different factors are passed to setRangeZoomFactor(double horizontalFact
Use the overload taking a list of axes, if multiple axes (more than one per orientation) shall react to zooming interactions.

See also

setRangeDragAxes

17.607.3.43 setRangeZoomAxes() [2/3]

```
void QCPAxisRect::setRangeZoomAxes (
            QList< QCPAxis * > axes )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This method allows to set up multiple axes to react to horizontal and vertical range zooming. The zoom orientation that the respective axis will react to is deduced from its orientation (QCPAxis::orientation).
In the unusual case that you wish to e.g. zoom a vertically oriented axis with a horizontal zoom interaction, use the overload taking two separate lists for horizontal and vertical zooming.

17.607.3.44 setRangeZoomAxes() [3/3]

```
void QCPAxisRect::setRangeZoomAxes (
            QList< QCPAxis * > horizontal,
            QList< QCPAxis * > vertical )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
This method allows to set multiple axes up to react to horizontal and vertical zooming, and define specifically which axis reacts to which zoom orientation (irrespective of the axis orientation).

17.607.3.45 setRangeZoomFactor() [1/2]

```
void QCPAxisRect::setRangeZoomFactor (
            double factor )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets both the horizontal and vertical zoom *factor*.

17.607.3.46 setRangeZoomFactor() [2/2]

```
void QCPAxisRect::setRangeZoomFactor (
            double horizontalFactor,
            double verticalFactor )
```

Sets how strong one rotation step of the mouse wheel zooms, when range zoom was activated with setRangeZoom. The two parameters *horizontalFactor* and *verticalFactor* provide a way to let the horizontal axis zoom at different rates than the vertical axis. Which axis is horizontal and which is vertical, can be set with setRangeZoomAxes.
When the zoom factor is greater than one, scrolling the mouse wheel backwards (towards the user) will zoom in (make the currently visible range smaller). For zoom factors smaller than one, the same scrolling direction will zoom out.

17.607.3.47 setupFullAxesBox()

```
void QCPAxisRect::setupFullAxesBox (
            bool connectRanges = false )
```

Convenience function to create an axis on each side that doesn't have any axes yet and set their visibility to true. Further, the top/right axes are assigned the following properties of the bottom/left axes:

- range (QCPAxis::setRange)
- range reversed (QCPAxis::setRangeReversed)
- scale type (QCPAxis::setScaleType)
- tick visibility (QCPAxis::setTicks)
- number format (QCPAxis::setNumberFormat)
- number precision (QCPAxis::setNumberPrecision)
- tick count of ticker (QCPAxisTicker::setTickCount)
- tick origin of ticker (QCPAxisTicker::setTickOrigin)

Tick label visibility (QCPAxis::setTickLabels) of the right and top axes are set to false.
If *connectRanges* is true, the rangeChanged signals of the bottom and left axes are connected to the QCPAxis::setRange slots of the top and right axes.

17.607.3.48 size()

```
QSize QCPAxisRect::size ( ) const  [inline]
```
Returns the pixel size of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.49 top()

```
int QCPAxisRect::top ( ) const  [inline]
```
Returns the pixel position of the top border of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.50 topLeft()

```
QPoint QCPAxisRect::topLeft ( ) const  [inline]
```
Returns the top left corner of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.51 topRight()

```
QPoint QCPAxisRect::topRight ( ) const  [inline]
```
Returns the top right corner of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.52 update()

```
void QCPAxisRect::update (
            UpdatePhase phase )  [virtual]
```
This method is called automatically upon replot and doesn't need to be called by users of QCPAxisRect.
Calls the base class implementation to update the margins (see QCPLayoutElement::update), and finally passes the rect to the inset layout (insetLayout) and calls its QCPInsetLayout::update function.
\seebaseclassmethod
Reimplemented from QCPLayoutElement.
Reimplemented in QCPColorScaleAxisRectPrivate.

17.607.3.53 wheelEvent()

```
void QCPAxisRect::wheelEvent (
            QWheelEvent * event )  [protected], [virtual]
```
This event gets called when the user turns the mouse scroll wheel while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`.
The `event->angleDelta()` indicates how far the mouse wheel was turned, which is usually +/- 120 for single rotation steps. However, if the mouse wheel is turned rapidly, multiple steps may accumulate to one event, making the delta larger. On the other hand, if the wheel has very smooth steps or none at all, the delta may be smaller.
The default implementation does nothing.

See also

mousePressEvent, mouseMoveEvent, mouseReleaseEvent, mouseDoubleClickEvent

Reimplemented from QCPLayerable.
Reimplemented in QCPColorScaleAxisRectPrivate.

17.607.3.54 width()

```
int QCPAxisRect::width ( ) const  [inline]
```
Returns the pixel width of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.607.3.55 zoom() [1/2]

```
void QCPAxisRect::zoom (
            const QRectF & pixelRect )
```

Zooms in (or out) to the passed rectangular region *pixelRect*, given in pixel coordinates.
All axes of this axis rect will have their range zoomed accordingly. If you only wish to zoom specific axes, use the overloaded version of this method.

See also

QCustomPlot::setSelectionRectMode

17.607.3.56 zoom() [2/2]

```
void QCPAxisRect::zoom (
            const QRectF & pixelRect,
            const QList< QCPAxis * > & affectedAxes )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Zooms in (or out) to the passed rectangular region *pixelRect*, given in pixel coordinates.
Only the axes passed in *affectedAxes* will have their ranges zoomed accordingly.

17.608.1 Detailed Description

The base class tick generator used by QCPAxis to create tick positions and tick labels.
Each QCPAxis has an internal QCPAxisTicker (or a subclass) in order to generate tick positions and tick labels for the current axis range. The ticker of an axis can be set via QCPAxis::setTicker. Since that method takes a `QSharedPointer<QCPAxisTicker>`, multiple axes can share the same ticker instance.
This base class generates normal tick coordinates and numeric labels for linear axes. It picks a reasonable tick step (the separation between ticks) which results in readable tick labels. The number of ticks that should be approximately generated can be set via setTickCount. Depending on the current tick step strategy (setTickStepStrategy), the algorithm either sacrifices readability to better match the specified tick count (QCPAxisTicker::tssMeetTickCount) or relaxes the tick count in favor of better tick steps (QCPAxisTicker::tssReadability), which is the default.
The following more specialized axis ticker subclasses are available, see details in the respective class documentation:

QCPAxisTickerFixed	td
QCPAxisTickerLog	td
QCPAxisTickerPi	td
QCPAxisTickerText	td
QCPAxisTickerDateTime	td
QCPAxisTickerTime	td

17.608.2 Creating own axis tickers

Creating own axis tickers can be achieved very easily by sublassing QCPAxisTicker and reimplementing some or all of the available virtual methods.
In the simplest case you might wish to just generate different tick steps than the other tickers, so you only reimplement the method getTickStep. If you additionally want control over the string that will be shown as tick label, reimplement getTickLabel.
If you wish to have complete control, you can generate the tick vectors and tick label vectors yourself by reimplementing createTickVector and createLabelVector. The default implementations use the previously mentioned virtual methods getTickStep and getTickLabel, but your reimplementations don't necessarily need to do so. For example in the case of unequal tick steps, the method getTickStep loses its usefulness and can be ignored.
The sub tick count between major ticks can be controlled with getSubTickCount. Full sub tick placement control is obtained by reimplementing createSubTickVector.
See the documentation of all these virtual methods in QCPAxisTicker for detailed information about the parameters and expected return values.

17.608.3 Member Enumeration Documentation

17.608.3.1 TickStepStrategy

`enum QCPAxisTicker::TickStepStrategy`
Defines the strategies that the axis ticker may follow when choosing the size of the tick step.

See also

setTickStepStrategy

Enumerator

tssReadability	A nicely readable tick step is prioritized over matching the requested number of ticks (see setTickCount)
tssMeetTickCount	Less readable tick steps are allowed which in turn facilitates getting closer to the requested tick count.

17.608.4 Constructor & Destructor Documentation

17.608.4.1 QCPAxisTicker()

```
QCPAxisTicker::QCPAxisTicker ( )
```
Constructs the ticker and sets reasonable default values. Axis tickers are commonly created managed by a QSharedPointer, which then can be passed to QCPAxis::setTicker.

17.608.5 Member Function Documentation

17.608.5.1 createTickVector()

```
QVector< double > QCPAxisTicker::createTickVector (
            double tickStep,
            const QCPRange & range )  [protected], [virtual]
```
Reimplemented in QCPAxisTickerText.

17.608.5.2 generate()

```
void QCPAxisTicker::generate (
            const QCPRange & range,
            const QLocale & locale,
```

```
            QChar formatChar,
            int precision,
            QVector< double > & ticks,
            QVector< double > * subTicks,
            QVector< QString > * tickLabels )  [virtual]
```

This is the method called by QCPAxis in order to actually generate tick coordinates (*ticks*), tick label strings (*tick↩ Labels*) and sub tick coordinates (*subTicks*).
The ticks are generated for the specified *range*. The generated labels typically follow the specified *locale*, *formatChar* and number *precision*, however this might be different (or even irrelevant) for certain QCPAxisTicker subclasses.
The output parameter *ticks* is filled with the generated tick positions in axis coordinates. The output parameters *subTicks* and *tickLabels* are optional (set them to `nullptr` if not needed) and are respectively filled with sub tick coordinates, and tick label strings belonging to *ticks* by index.

17.608.5.3 getSubTickCount()

```
int QCPAxisTicker::getSubTickCount (
            double tickStep )  [protected], [virtual]
```

Reimplemented in QCPAxisTickerText.

17.608.5.4 getTickLabel()

```
QString QCPAxisTicker::getTickLabel (
            double tick,
            const QLocale & locale,
            QChar formatChar,
            int precision )  [protected], [virtual]
```

Reimplemented in QCPAxisTickerText.

17.608.5.5 getTickStep()

```
double QCPAxisTicker::getTickStep (
            const QCPRange & range )  [protected], [virtual]
```

Reimplemented in QCPAxisTickerText.

17.608.5.6 setTickCount()

```
void QCPAxisTicker::setTickCount (
            int count )
```

Sets how many ticks this ticker shall aim to generate across the axis range. Note that *count* is not guaranteed to be matched exactly, as generating readable tick intervals may conflict with the requested number of ticks.
Whether the readability has priority over meeting the requested *count* can be specified with setTickStepStrategy.

17.608.5.7 setTickOrigin()

```
void QCPAxisTicker::setTickOrigin (
            double origin )
```

Sets the mathematical coordinate (or "offset") of the zeroth tick. This tick coordinate is just a concept and doesn't need to be inside the currently visible axis range.
By default *origin* is zero, which for example yields ticks {-5, 0, 5, 10, 15,...} when the tick step is five. If *origin* is now set to 1 instead, the correspondingly generated ticks would be {-4, 1, 6, 11, 16,...}.

17.608.5.8 setTickStepStrategy()

```
void QCPAxisTicker::setTickStepStrategy (
            QCPAxisTicker::TickStepStrategy strategy )
```

Sets which strategy the axis ticker follows when choosing the size of the tick step. For the available strategies, see TickStepStrategy.

17.609.1 Detailed Description

Specialized axis ticker for calendar dates and times as axis ticks.
This QCPAxisTicker subclass generates ticks that correspond to real calendar dates and times. The plot axis coordinate is interpreted as Unix Time, so seconds since Epoch (January 1, 1970, 00:00 UTC). This is also used for example by QDateTime in the `toTime_t()/setTime_t()` methods with a precision of one second. Since Qt 4.7, millisecond accuracy can be obtained from QDateTime by using `QDateTime::fromMSecsSinceEpoch()/1000.0`. The static methods dateTimeToKey and keyToDateTime conveniently perform this conversion achieving a precision of one millisecond on all Qt versions.
The format of the date/time display in the tick labels is controlled with setDateTimeFormat. If a different time spec or time zone shall be used for the tick label appearance, see setDateTimeSpec or setTimeZone, respectively.
This ticker produces unequal tick spacing in order to provide intuitive date and time-of-day ticks. For example, if the axis range spans a few years such that there is one tick per year, ticks will be positioned on 1. January of every year. This is intuitive but, due to leap years, will result in slightly unequal tick intervals (visually unnoticeable). The same can be seen in the image above: even though the number of days varies month by month, this ticker generates ticks on the same day of each month.
If you would like to change the date/time that is used as a (mathematical) starting date for the ticks, use the setTickOrigin(const QDateTime &origin) method overload, which takes a QDateTime. If you pass 15. July, 9:45 to this method, the yearly ticks will end up on 15. July at 9:45 of every year.
The ticker can be created and assigned to an axis like this:

Note

> If you rather wish to display relative times in terms of days, hours, minutes, seconds and milliseconds, and are not interested in the intricacies of real calendar dates with months and (leap) years, have a look at QCPAxisTickerTime instead.

17.609.2 Constructor & Destructor Documentation

17.609.2.1 QCPAxisTickerDateTime()

```
QCPAxisTickerDateTime::QCPAxisTickerDateTime ( )
```

Constructs the ticker and sets reasonable default values. Axis tickers are commonly created managed by a QSharedPointer, which then can be passed to QCPAxis::setTicker.

17.609.3 Member Function Documentation

17.609.3.1 createTickVector()

```
QVector< double > QCPAxisTickerDateTime::createTickVector (
            double tickStep,
            const QCPRange & range )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.609.3.2 dateTimeToKey() [1/2]

```
double QCPAxisTickerDateTime::dateTimeToKey (
            const QDate & date,
            Qt::TimeSpec timeSpec = Qt::LocalTime )  [static]
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
A convenience method which turns a QDate object into a double value that corresponds to seconds since Epoch (1. Jan 1970, 00:00 UTC). This is the format used as axis coordinates by QCPAxisTickerDateTime.
The returned value will be the start of the passed day of *date*, interpreted in the given *timeSpec*.

See also

> keyToDateTime

17.609.3.3 dateTimeToKey() [2/2]

```
double QCPAxisTickerDateTime::dateTimeToKey (
            const QDateTime & dateTime )  [static]
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
A convenience method which turns a QDateTime object into a double value that corresponds to seconds since Epoch (1. Jan 1970, 00:00 UTC). This is the format used as axis coordinates by QCPAxisTickerDateTime.
The accuracy achieved by this method is one millisecond, irrespective of the used Qt version (it works around the lack of a QDateTime::toMSecsSinceEpoch in Qt 4.6)

See also

keyToDateTime

17.609.3.4 getSubTickCount()

```
int QCPAxisTickerDateTime::getSubTickCount (
            double tickStep )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.609.3.5 getTickLabel()

```
QString QCPAxisTickerDateTime::getTickLabel (
            double tick,
            const QLocale & locale,
            QChar formatChar,
            int precision )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.609.3.6 getTickStep()

```
double QCPAxisTickerDateTime::getTickStep (
            const QCPRange & range )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.609.3.7 keyToDateTime()

```
QDateTime QCPAxisTickerDateTime::keyToDateTime (
            double key )  [static]
```

A convenience method which turns *key* (in seconds since Epoch 1. Jan 1970, 00:00 UTC) into a QDateTime object. This can be used to turn axis coordinates to actual QDateTimes.
The accuracy achieved by this method is one millisecond, irrespective of the used Qt version (it works around the lack of a QDateTime::fromMSecsSinceEpoch in Qt 4.6)

See also

dateTimeToKey

17.609.3.8 setDateTimeFormat()

```
void QCPAxisTickerDateTime::setDateTimeFormat (
            const QString & format )
```

Sets the format in which dates and times are displayed as tick labels. For details about the *format* string, see the documentation of QDateTime::toString().
Typical expressions are

d	The day as a number without a leading zero (1 to 31)
dd	The day as a number with a leading zero (01 to 31)
ddd	The abbreviated localized day name (e.g. 'Mon' to 'Sun'). Uses the system locale to localize the name, i.e. QLocale::system().
dddd	The long localized day name (e.g. 'Monday' to 'Sunday'). Uses the system locale to localize the name, i.e. QLocale::system().
M	The month as a number without a leading zero (1 to 12)
MM	The month as a number with a leading zero (01 to 12)
MMM	The abbreviated localized month name (e.g. 'Jan' to 'Dec'). Uses the system locale to localize the name, i.e. QLocale::system().
MMMM	The long localized month name (e.g. 'January' to 'December'). Uses the system locale to localize the name, i.e. QLocale::system().
yy	The year as a two digit number (00 to 99)
yyyy	The year as a four digit number. If the year is negative, a minus sign is prepended, making five characters.
h	The hour without a leading zero (0 to 23 or 1 to 12 if AM/PM display)
hh	The hour with a leading zero (00 to 23 or 01 to 12 if AM/PM display)
H	The hour without a leading zero (0 to 23, even with AM/PM display)
HH	The hour with a leading zero (00 to 23, even with AM/PM display)
m	The minute without a leading zero (0 to 59)
mm	The minute with a leading zero (00 to 59)
s	The whole second, without any leading zero (0 to 59)
ss	The whole second, with a leading zero where applicable (00 to 59)
z	The fractional part of the second, to go after a decimal point, without trailing zeroes (0 to 999). Thus "s.z" reports the seconds to full available (millisecond) precision without trailing zeroes.
zzz	The fractional part of the second, to millisecond precision, including trailing zeroes where applicable (000 to 999).
AP or A	Use AM/PM display. A/AP will be replaced by an upper-case version of either QLocale::amText() or QLocale::pmText().
ap or a	Use am/pm display. a/ap will be replaced by a lower-case version of either QLocale::amText() or QLocale::pmText().
t	The timezone (for example "CEST")

Newlines can be inserted with "\n", literal strings (even when containing above expressions) by encapsulating them using single-quotes. A literal single quote can be generated by using two consecutive single quotes in the format.

See also

setDateTimeSpec, setTimeZone

17.609.3.9 setDateTimeSpec()

```
void QCPAxisTickerDateTime::setDateTimeSpec (
            Qt::TimeSpec spec )
```

Sets the time spec that is used for creating the tick labels from corresponding dates/times.
The default value of QDateTime objects (and also QCPAxisTickerDateTime) is Qt::LocalTime. However, if the displayed tick labels shall be given in UTC, set *spec* to Qt::UTC.
Tick labels corresponding to other time zones can be achieved with setTimeZone (which sets *spec* to Qt::TimeZone internally). Note that if *spec* is afterwards set to not be Qt::TimeZone again, the setTimeZone setting will be ignored accordingly.

See also

setDateTimeFormat, setTimeZone

17.609.3.10 setTickOrigin() [1/2]

```
void QCPAxisTickerDateTime::setTickOrigin (
            const QDateTime & origin )
```

Sets the tick origin (see QCPAxisTicker::setTickOrigin) as a QDateTime *origin*.
This is useful to define the month/day/time recurring at greater tick interval steps. For example, If you pass 15. July, 9:45 to this method and the tick interval happens to be one tick per year, the ticks will end up on 15. July at 9:45 of every year.

17.609.3.11 setTickOrigin() [2/2]

```
void QCPAxisTickerDateTime::setTickOrigin (
            double origin )
```

Sets the tick origin (see QCPAxisTicker::setTickOrigin) in seconds since Epoch (1. Jan 1970, 00:00 UTC). For the date time ticker it might be more intuitive to use the overload which directly takes a QDateTime, see setTickOrigin(const QDateTime &origin).
This is useful to define the month/day/time recurring at greater tick interval steps. For example, If you pass 15. July, 9:45 to this method and the tick interval happens to be one tick per year, the ticks will end up on 15. July at 9:45 of every year.

17.609.3.12 setTimeZone()

```
void QCPAxisTickerDateTime::setTimeZone (
            const QTimeZone & zone )
```

Sets the time zone that is used for creating the tick labels from corresponding dates/times. The time spec (setDateTimeSpec) is set to `Qt::TimeZone`.

17.610.1 Detailed Description

Specialized axis ticker with a fixed tick step.
This QCPAxisTicker subclass generates ticks with a fixed tick step set with setTickStep. It is also possible to allow integer multiples and integer powers of the specified tick step with setScaleStrategy.
A typical application of this ticker is to make an axis only display integers, by setting the tick step of the ticker to 1.0 and the scale strategy to ssMultiples.
Another case is when a certain number has a special meaning and axis ticks should only appear at multiples of that value. In this case you might also want to consider QCPAxisTickerPi because despite the name it is not limited to only pi symbols/values.
The ticker can be created and assigned to an axis like this:

17.610.2 Member Enumeration Documentation

17.610.2.1 ScaleStrategy

`enum QCPAxisTickerFixed::ScaleStrategy`
Defines how the axis ticker may modify the specified tick step (setTickStep) in order to control the number of ticks in the axis range.

See also

setScaleStrategy

Enumerator

ssNone	Modifications are not allowed, the specified tick step is absolutely fixed. This might cause a high tick density and overlapping labels if the axis range is zoomed out.
ssMultiples	An integer multiple of the specified tick step is allowed. The used factor follows the base class properties of setTickStepStrategy and setTickCount.
ssPowers	An integer power of the specified tick step is allowed.

17.610.3 Constructor & Destructor Documentation

17.610.3.1 QCPAxisTickerFixed()

`QCPAxisTickerFixed::QCPAxisTickerFixed ( )`
Constructs the ticker and sets reasonable default values. Axis tickers are commonly created managed by a QSharedPointer, which then can be passed to QCPAxis::setTicker.

17.610.4 Member Function Documentation

17.610.4.1 getTickStep()

```
double QCPAxisTickerFixed::getTickStep (
            const QCPRange & range )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.610.4.2 setScaleStrategy()

```
void QCPAxisTickerFixed::setScaleStrategy (
            QCPAxisTickerFixed::ScaleStrategy strategy )
```

Sets whether the specified tick step (setTickStep) is absolutely fixed or whether modifications may be applied to it before calculating the finally used tick step, such as permitting multiples or powers. See ScaleStrategy for details.
The default strategy is ssNone, which means the tick step is absolutely fixed.

17.610.4.3 setTickStep()

```
void QCPAxisTickerFixed::setTickStep (
            double step )
```

Sets the fixed tick interval to *step*.
The axis ticker will only use this tick step when generating axis ticks. This might cause a very high tick density and overlapping labels if the axis range is zoomed out. Using setScaleStrategy it is possible to relax the fixed step and also allow multiples or powers of *step*. This will enable the ticker to reduce the number of ticks to a reasonable amount (see setTickCount).
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.611.1 Detailed Description

Specialized axis ticker suited for logarithmic axes.
This QCPAxisTicker subclass generates ticks with unequal tick intervals suited for logarithmic axis scales. The ticks are placed at powers of the specified log base (setLogBase).
Especially in the case of a log base equal to 10 (the default), it might be desirable to have tick labels in the form of powers of ten without mantissa display. To achieve this, set the number precision (QCPAxis::setNumberPrecision) to zero and the number format (QCPAxis::setNumberFormat) to scientific (exponential) display with beautifully typeset decimal powers, so a format string of `"eb"`. This will result in the following axis tick labels:
The ticker can be created and assigned to an axis like this:
Note that the nature of logarithmic ticks imply that there exists a smallest possible tick step, corresponding to one multiplication by the log base. If the user zooms in further than that, no new ticks would appear, leading to very sparse or even no axis ticks on the axis. To prevent this situation, this ticker falls back to regular tick generation if the axis range would be covered by too few logarithmically placed ticks.

17.611.2 Constructor & Destructor Documentation

17.611.2.1 QCPAxisTickerLog()

```
QCPAxisTickerLog::QCPAxisTickerLog ( )
```

Constructs the ticker and sets reasonable default values. Axis tickers are commonly created managed by a QSharedPointer, which then can be passed to QCPAxis::setTicker.

17.611.3 Member Function Documentation

17.611.3.1 createTickVector()

```
QVector< double > QCPAxisTickerLog::createTickVector (
            double tickStep,
            const QCPRange & range )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.611.3.2 getSubTickCount()

```
int QCPAxisTickerLog::getSubTickCount (
            double tickStep )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.611.3.3 setLogBase()

```
void QCPAxisTickerLog::setLogBase (
            double base )
```

Sets the logarithm base used for tick coordinate generation. The ticks will be placed at integer powers of *base*.

17.611.3.4 setSubTickCount()

```
void QCPAxisTickerLog::setSubTickCount (
            int subTicks )
```

Sets the number of sub ticks in a tick interval. Within each interval, the sub ticks are spaced linearly to provide a better visual guide, so the sub tick density increases toward the higher tick.
Note that *subTicks* is the number of sub ticks (not sub intervals) in one tick interval. So in the case of logarithm base 10 an intuitive sub tick spacing would be achieved with eight sub ticks (the default). This means e.g. between the ticks 10 and 100 there will be eight ticks, namely at 20, 30, 40, 50, 60, 70, 80 and 90.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.612 QCPAxisTickerPi Class Reference

Specialized axis ticker to display ticks in units of an arbitrary constant, for example pi.

17.612.1 Detailed Description

Specialized axis ticker to display ticks in units of an arbitrary constant, for example pi.
This QCPAxisTicker subclass generates ticks that are expressed with respect to a given symbolic constant with a numerical value specified with setPiValue and an appearance in the tick labels specified with setPiSymbol.
Ticks may be generated at fractions of the symbolic constant. How these fractions appear in the tick label can be configured with setFractionStyle.
The ticker can be created and assigned to an axis like this:

17.612.2 Member Enumeration Documentation

17.612.2.1 FractionStyle

```
enum QCPAxisTickerPi::FractionStyle
```
Defines how fractions should be displayed in tick labels.

See also

setFractionStyle

Enumerator

fsFloatingPoint	Fractions are displayed as regular decimal floating point numbers, e.g. "0.25" or "0.125".
fsAsciiFractions	Fractions are written as rationals using ASCII characters only, e.g. "1/4" or "1/8".
fsUnicodeFractions	Fractions are written using sub- and superscript UTF-8 digits and the fraction symbol.

17.612.3 Constructor & Destructor Documentation

17.612.3.1 QCPAxisTickerPi()

```
QCPAxisTickerPi::QCPAxisTickerPi ( )
```
Constructs the ticker and sets reasonable default values. Axis tickers are commonly created managed by a QSharedPointer, which then can be passed to QCPAxis::setTicker.

17.612.4 Member Function Documentation

17.612.4.1 getSubTickCount()

```
int QCPAxisTickerPi::getSubTickCount (
            double tickStep )  [protected], [virtual]
```
Reimplemented from QCPAxisTicker.

17.612.4.2 getTickLabel()

```
QString QCPAxisTickerPi::getTickLabel (
            double tick,
            const QLocale & locale,
            QChar formatChar,
            int precision )  [protected], [virtual]
```
Reimplemented from QCPAxisTicker.

17.612.4.3 getTickStep()

```
double QCPAxisTickerPi::getTickStep (
            const QCPRange & range )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.612.4.4 setFractionStyle()

```
void QCPAxisTickerPi::setFractionStyle (
            QCPAxisTickerPi::FractionStyle style )
```

Sets how the numerical/fractional part preceding the symbolic constant is displayed in tick labels. See FractionStyle for the various options.

17.612.4.5 setPeriodicity()

```
void QCPAxisTickerPi::setPeriodicity (
            int multiplesOfPi )
```

Sets whether the axis labels shall appear periodicly and if so, at which multiplicity of the symbolic constant.
To disable periodicity, set *multiplesOfPi* to zero.
For example, an axis that identifies 0 with 2pi would set *multiplesOfPi* to two.

17.612.4.6 setPiSymbol()

```
void QCPAxisTickerPi::setPiSymbol (
            QString symbol )
```

Sets how the symbol part (which is always a suffix to the number) shall appear in the axis tick label.
If a space shall appear between the number and the symbol, make sure the space is contained in *symbol*.

17.612.4.7 setPiValue()

```
void QCPAxisTickerPi::setPiValue (
            double pi )
```

Sets the numerical value that the symbolic constant has.
This will be used to place the appropriate fractions of the symbol at the respective axis coordinates.

17.613.1 Detailed Description

Specialized axis ticker which allows arbitrary labels at specified coordinates.
This QCPAxisTicker subclass generates ticks which can be directly specified by the user as coordinates and associated strings. They can be passed as a whole with setTicks or one at a time with addTick. Alternatively you can directly access the internal storage via ticks and modify the tick/label data there.
This is useful for cases where the axis represents categories rather than numerical values.
If you are updating the ticks of this ticker regularly and in a dynamic fasion (e.g. dependent on the axis range), it is a sign that you should probably create an own ticker by subclassing QCPAxisTicker, instead of using this one.
The ticker can be created and assigned to an axis like this:

17.613.2 Constructor & Destructor Documentation

17.613.2.1 QCPAxisTickerText()

```
QCPAxisTickerText::QCPAxisTickerText ( )
```

Constructs the ticker and sets reasonable default values. Axis tickers are commonly created managed by a QSharedPointer, which then can be passed to QCPAxis::setTicker.

17.613.3 Member Function Documentation

17.613.3.1 addTick()

```
void QCPAxisTickerText::addTick (
            double position,
            const QString & label )
```

Adds a single tick to the axis at the given axis coordinate *position*, with the provided tick *label*.

See also

addTicks, setTicks, clear

17.613.3.2 addTicks() [1/2]

```
void QCPAxisTickerText::addTicks (
            const QMap< double, QString > & ticks )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Adds the provided *ticks* to the ones already existing. The map key of *ticks* corresponds to the axis coordinate, and the map value is the string that will appear as tick label.
An alternative to manipulate ticks is to directly access the internal storage with the ticks getter.

See also

addTick, setTicks, clear

17.613.3.3 addTicks() [2/2]

```
void QCPAxisTickerText::addTicks (
            const QVector< double > & positions,
            const QVector< QString > & labels )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds the provided ticks to the ones already existing. The entries of *positions* correspond to the axis coordinates, and the entries of *labels* are the respective strings that will appear as tick labels.
An alternative to manipulate ticks is to directly access the internal storage with the ticks getter.

See also

addTick, setTicks, clear

17.613.3.4 clear()

```
void QCPAxisTickerText::clear ( )
```

Clears all ticks.
An alternative to manipulate ticks is to directly access the internal storage with the ticks getter.

See also

setTicks, addTicks, addTick

17.613.3.5 createTickVector()

```
QVector< double > QCPAxisTickerText::createTickVector (
            double tickStep,
            const QCPRange & range )  [protected], [virtual]
```

Returns the externally provided tick coordinates which are in the specified *range*. If available, one tick above and below the range is provided in addition, to allow possible sub tick calculation. The parameter *tickStep* is ignored.
\seebaseclassmethod
Reimplemented from QCPAxisTicker.

17.613.3.6 getSubTickCount()

```
int QCPAxisTickerText::getSubTickCount (
            double tickStep )  [protected], [virtual]
```

Returns the sub tick count that was configured with setSubTickCount.
\seebaseclassmethod
Reimplemented from QCPAxisTicker.

17.613.3.7 getTickLabel()

```
QString QCPAxisTickerText::getTickLabel (
            double tick,
            const QLocale & locale,
            QChar formatChar,
            int precision )  [protected], [virtual]
```

Returns the tick label which corresponds to the key *tick* in the internal tick storage. Since the labels are provided externally, *locale*, *formatChar*, and *precision* are ignored.
\seebaseclassmethod
Reimplemented from QCPAxisTicker.

17.613.3.8 getTickStep()

```
double QCPAxisTickerText::getTickStep (
            const QCPRange & range )  [protected], [virtual]
```

Since the tick coordinates are provided externally, this method implementation does nothing.
\seebaseclassmethod
Reimplemented from QCPAxisTicker.

17.613.3.9 setSubTickCount()

```
void QCPAxisTickerText::setSubTickCount (
            int subTicks )
```

Sets the number of sub ticks that shall appear between ticks. For QCPAxisTickerText, there is no automatic sub tick count calculation. So if sub ticks are needed, they must be configured with this method.

17.613.3.10 setTicks() [1/2]

```
void QCPAxisTickerText::setTicks (
            const QMap< double, QString > & ticks )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the ticks that shall appear on the axis. The map key of *ticks* corresponds to the axis coordinate, and the map value is the string that will appear as tick label.
An alternative to manipulate ticks is to directly access the internal storage with the ticks getter.

See also

addTicks, addTick, clear

17.613.3.11 setTicks() [2/2]

```
void QCPAxisTickerText::setTicks (
            const QVector< double > & positions,
            const QVector< QString > & labels )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the ticks that shall appear on the axis. The entries of *positions* correspond to the axis coordinates, and the entries of *labels* are the respective strings that will appear as tick labels.

See also

addTicks, addTick, clear

17.613.3.12 ticks()

```
QMap< double, QString > & QCPAxisTickerText::ticks ( )  [inline]
```

Returns a non-const reference to the internal map which stores the tick coordinates and their labels.
You can access the map directly in order to add, remove or manipulate ticks, as an alternative to using the methods provided by QCPAxisTickerText, such as setTicks and addTick.

17.614.1 Detailed Description

Specialized axis ticker for time spans in units of milliseconds to days.
This QCPAxisTicker subclass generates ticks that corresponds to time intervals.
The format of the time display in the tick labels is controlled with setTimeFormat and setFieldWidth. The time coordinate is in the unit of seconds with respect to the time coordinate zero. Unlike with QCPAxisTickerDateTime, the ticks don't correspond to a specific calendar date and time.
The time can be displayed in milliseconds, seconds, minutes, hours and days. Depending on the largest available unit in the format specified with setTimeFormat, any time spans above will be carried in that largest unit. So for example if the format string is "%m:%s" and a tick at coordinate value 7815 (being 2 hours, 10 minutes and 15 seconds) is created, the resulting tick label will show "130:15" (130 minutes, 15 seconds). If the format string is "%h:%m:%s", the hour unit will be used and the label will thus be "02:10:15". Negative times with respect to the axis zero will carry a leading minus sign.
The ticker can be created and assigned to an axis like this:
Here is an example of a time axis providing time information in days, hours and minutes. Due to the axis range spanning a few days and the wanted tick count (setTickCount), the ticker decided to use tick steps of 12 hours:
The format string for this example is

Note

If you rather wish to display calendar dates and times, have a look at QCPAxisTickerDateTime instead.

17.614.2 Member Enumeration Documentation

17.614.2.1 TimeUnit

`enum QCPAxisTickerTime::TimeUnit`

Defines the logical units in which fractions of time spans can be expressed.

See also

setFieldWidth, setTimeFormat

Enumerator

tuMilliseconds	Milliseconds, one thousandth of a second (%z in setTimeFormat)
tuSeconds	Seconds (%s in setTimeFormat)
tuMinutes	Minutes (%m in setTimeFormat)
tuHours	Hours (%h in setTimeFormat)
tuDays	Days (%d in setTimeFormat)

17.614.3 Constructor & Destructor Documentation

17.614.3.1 QCPAxisTickerTime()

```
QCPAxisTickerTime::QCPAxisTickerTime ( )
```

Constructs the ticker and sets reasonable default values. Axis tickers are commonly created managed by a QSharedPointer, which then can be passed to QCPAxis::setTicker.

17.614.4 Member Function Documentation

17.614.4.1 getSubTickCount()

```
int QCPAxisTickerTime::getSubTickCount (
            double tickStep )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.614.4.2 getTickLabel()

```
QString QCPAxisTickerTime::getTickLabel (
            double tick,
            const QLocale & locale,
            QChar formatChar,
            int precision )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.614.4.3 getTickStep()

```
double QCPAxisTickerTime::getTickStep (
            const QCPRange & range )  [protected], [virtual]
```

Reimplemented from QCPAxisTicker.

17.614.4.4 setFieldWidth()

```
void QCPAxisTickerTime::setFieldWidth (
            QCPAxisTickerTime::TimeUnit unit,
            int width )
```

Sets the field widh of the specified *unit* to be *width* digits, when displayed in the tick label. If the number for the specific unit is shorter than *width*, it will be padded with an according number of zeros to the left in order to reach the field width.

See also

setTimeFormat

17.614.4.5 setTimeFormat()

```
void QCPAxisTickerTime::setTimeFormat (
            const QString & format )
```

Sets the format that will be used to display time in the tick labels.
The available patterns are:

- %z for milliseconds
- %s for seconds
- %m for minutes
- %h for hours
- %d for days

The field width (zero padding) can be controlled for each unit with setFieldWidth.
The largest unit that appears in *format* will carry all the remaining time of a certain tick coordinate, even if it overflows the natural limit of the unit. For example, if %m is the largest unit it might become larger than 59 in order to consume larger time values. If on the other hand %h is available, the minutes will wrap around to zero after 59 and the time will carry to the hour digit.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.615.1 Detailed Description

A plottable representing a bar chart in a plot.
To plot data, assign it with the setData or addData functions.

17.615.2 Changing the appearance

The appearance of the bars is determined by the pen and the brush (setPen, setBrush). The width of the individual bars can be controlled with setWidthType and setWidth.
Bar charts are stackable. This means, two QCPBars plottables can be placed on top of each other (see QCPBars::moveAbove). So when two bars are at the same key position, they will appear stacked.
If you would like to group multiple QCPBars plottables together so they appear side by side as shown below, use QCPBarsGroup.

17.615.3 Usage

Like all data representing objects in QCustomPlot, the QCPBars is a plottable (QCPAbstractPlottable). So the plottable-interface of QCustomPlot applies (QCustomPlot::plottable, QCustomPlot::removePlottable, etc.)
Usually, you first create an instance:
which registers it with the QCustomPlot instance of the passed axes. Note that this QCustomPlot instance takes ownership of the plottable, so do not delete it manually but use QCustomPlot::removePlottable() instead. The newly created plottable can be modified, e.g.:

17.615.4 Member Enumeration Documentation

17.615.4.1 WidthType

`enum QCPBars::WidthType`
Defines the ways the width of the bar can be specified. Thus it defines what the number passed to setWidth actually means.

See also

setWidthType, setWidth

Enumerator

wtAbsolute	Bar width is in absolute pixels.
wtAxisRectRatio	Bar width is given by a fraction of the axis rect size.
wtPlotCoords	Bar width is in key coordinates and thus scales with the key axis range.

17.615.5 Constructor & Destructor Documentation

17.615.5.1 QCPBars()

```
QCPBars::QCPBars (
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )  [explicit]
```

Constructs a bar chart which uses *keyAxis* as its key axis ("x") and *valueAxis* as its value axis ("y"). *keyAxis* and *valueAxis* must reside in the same QCustomPlot instance and not have the same orientation. If either of these restrictions is violated, a corresponding message is printed to the debug output (qDebug), the construction is not aborted, though.
The created QCPBars is automatically registered with the QCustomPlot instance inferred from *keyAxis*. This QCustomPlot instance takes ownership of the QCPBars, so do not delete it manually but use QCustomPlot::removePlottable() instead.

17.615.6 Member Function Documentation

17.615.6.1 addData() [1/2]

```
void QCPBars::addData (
            const QVector< double > & keys,
            const QVector< double > & values,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds the provided points in *keys* and *values* to the current data. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.
If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.
Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.615.6.2 addData() [2/2]

```
void QCPBars::addData (
            double key,
            double value )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. Adds the provided data point as *key* and *value* to the current data.
Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.615.6.3 barAbove()

```
QCPBars * QCPBars::barAbove ( ) const  [inline]
```

Returns the bars plottable that is directly above this bars plottable. If there is no such plottable, returns `nullptr`.

See also

barBelow, moveBelow, moveAbove

17.615.6.4 barBelow()

```
QCPBars * QCPBars::barBelow ( ) const  [inline]
```
Returns the bars plottable that is directly below this bars plottable. If there is no such plottable, returns `nullptr`.

See also

barAbove, moveBelow, moveAbove

17.615.6.5 data()

```
QSharedPointer< QCPBarsDataContainer > QCPBars::data ( ) const  [inline]
```
Returns a shared pointer to the internal data storage of type QCPBarsDataContainer. You may use it to directly manipulate the data, which may be more convenient and faster than using the regular setData or addData methods.

17.615.6.6 dataPixelPosition()

```
QPointF QCPBars::dataPixelPosition (
            int index ) const  [virtual]
```
Returns the pixel position on the widget surface at which the data point at the given *index* appears.
Usually this corresponds to the point of dataMainKey/ dataMainValue, in pixel coordinates. However, depending on the plottable, this might be a different apparent position than just a coord-to-pixel transform of those values. For example, QCPBars apparent data values can be shifted depending on their stacking, bar grouping or configured base value.
Reimplemented from QCPAbstractPlottable1D< QCPBarsData >.

17.615.6.7 draw()

```
void QCPBars::draw (
            QCPPainter * painter )  [protected], [virtual]
```
Implements QCPAbstractPlottable.

17.615.6.8 drawLegendIcon()

```
void QCPBars::drawLegendIcon (
            QCPPainter * painter,
            const QRectF & rect ) const  [protected], [virtual]
```
Implements QCPAbstractPlottable.

17.615.6.9 getKeyRange()

```
QCPRange QCPBars::getKeyRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth ) const  [virtual]
```
Returns the coordinate range that all data in this plottable span in the key axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSignDomain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getValueRange

Implements QCPAbstractPlottable.

17.615.6.10 getValueRange()

```
QCPRange QCPBars::getValueRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth,
            const QCPRange & inKeyRange = QCPRange() ) const  [virtual]
```

Returns the coordinate range that the data points in the specified key range (*inKeyRange*) span in the value axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSign↩ Domain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
If *inKeyRange* has both lower and upper bound set to zero (is equal to `QCPRange()`), all data points are considered, without any restriction on the keys.
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getKeyRange

Implements QCPAbstractPlottable.

17.615.6.11 moveAbove()

```
void QCPBars::moveAbove (
            QCPBars * bars )
```

Moves this bars plottable above *bars*. In other words, the bars of this plottable will appear above the bars of *bars*. The move target *bars* must use the same key and value axis as this plottable.
Inserting into and removing from existing bar stacking is handled gracefully. If *bars* already has a bars object above itself, this bars object is inserted between the two. If this bars object is already between two other bars, the two other bars will be stacked on top of each other after the operation.
To remove this bars plottable from any stacking, set *bars* to `nullptr`.

See also

moveBelow, barBelow, barAbove

17.615.6.12 moveBelow()

```
void QCPBars::moveBelow (
            QCPBars * bars )
```

Moves this bars plottable below *bars*. In other words, the bars of this plottable will appear below the bars of *bars*. The move target *bars* must use the same key and value axis as this plottable.
Inserting into and removing from existing bar stacking is handled gracefully. If *bars* already has a bars object below itself, this bars object is inserted between the two. If this bars object is already between two other bars, the two other bars will be stacked on top of each other after the operation.
To remove this bars plottable from any stacking, set *bars* to `nullptr`.

See also

moveBelow, barAbove, barBelow

17.615.6.13 selectTest()

```
double QCPBars::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Implements a selectTest specific to this plottable's point geometry.

If *details* is not 0, it will be set to a QCPDataSelection, describing the closest data point to *pos*.
\seebaseclassmethod QCPAbstractPlottable::selectTest
Reimplemented from QCPAbstractPlottable1D< QCPBarsData >.

17.615.6.14 selectTestRect()

```
QCPDataSelection QCPBars::selectTestRect (
            const QRectF & rect,
            bool onlySelectable ) const  [virtual]
```

Returns a data selection containing all the data points of this plottable which are contained (or hit by) *rect*. This is used mainly in the selection rect interaction for data selection (data selection mechanism).
If *onlySelectable* is true, an empty QCPDataSelection is returned if this plottable is not selectable (i.e. if QCPAbstractPlottable::setSelectable is QCP::stNone).

Note

> *rect* must be a normalized rect (positive or zero width and height). This is especially important when using the rect of QCPSelectionRect::accepted, which is not necessarily normalized. Use `QRect::normalized()` when passing a rect which might not be normalized.

Reimplemented from QCPAbstractPlottable1D< QCPBarsData >.

17.615.6.15 setBarsGroup()

```
void QCPBars::setBarsGroup (
            QCPBarsGroup * barsGroup )
```

Sets to which QCPBarsGroup this QCPBars instance belongs to. Alternatively, you can also use QCPBarsGroup::append.
To remove this QCPBars from any group, set *barsGroup* to `nullptr`.

17.615.6.16 setBaseValue()

```
void QCPBars::setBaseValue (
            double baseValue )
```

Sets the base value of this bars plottable.
The base value defines where on the value coordinate the bars start. How far the bars extend from the base value is given by their individual value data. For example, if the base value is set to 1, a bar with data value 2 will have its lowest point at value coordinate 1 and highest point at 3.
For stacked bars, only the base value of the bottom-most QCPBars has meaning.
The default base value is 0.

17.615.6.17 setData() [1/2]

```
void QCPBars::setData (
            const QVector< double > & keys,
            const QVector< double > & values,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data with the provided points in *keys* and *values*. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.
If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.

See also

> addData

17.615.6.18 setData() [2/2]

```
void QCPBars::setData (
            QSharedPointer< QCPBarsDataContainer > data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data container with the provided *data* container.
Since a QSharedPointer is used, multiple QCPBars may share the same data container safely. Modifying the data in the container will then affect all bars that share the container. Sharing can be achieved by simply exchanging the data containers wrapped in shared pointers:
If you do not wish to share containers, but create a copy from an existing container, rather use the QCPDataContainer<DataType>::set method on the bar's data container directly:

See also

addData

17.615.6.19 setStackingGap()

```
void QCPBars::setStackingGap (
            double pixels )
```

If this bars plottable is stacked on top of another bars plottable (moveAbove), this method allows specifying a distance in *pixels*, by which the drawn bar rectangles will be separated by the bars below it.

17.615.6.20 setWidth()

```
void QCPBars::setWidth (
            double width )
```

Sets the width of the bars.
How the number passed as *width* is interpreted (e.g. screen pixels, plot coordinates,...), depends on the currently set width type, see setWidthType and WidthType.

17.615.6.21 setWidthType()

```
void QCPBars::setWidthType (
            QCPBars::WidthType widthType )
```

Sets how the width of the bars is defined. See the documentation of WidthType for an explanation of the possible values for *widthType*.
The default value is wtPlotCoords.

See also

setWidth

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.616 QCPBarsData Class Reference

Holds the data of one single data point (one bar) for QCPBars.

Public Member Functions

- QCPBarsData ()
- QCPBarsData (double key, double value)
- double sortKey () const
- double mainKey () const
- double mainValue () const
- QCPRange valueRange () const

Static Public Member Functions

- static QCPBarsData fromSortKey (double sortKey)
- static bool sortKeyIsMainKey ()

Public Attributes

- double **key**
- double **value**

17.616.1 Detailed Description

Holds the data of one single data point (one bar) for QCPBars.
The stored data is:

- *key:* coordinate on the key axis of this bar (this is the *mainKey* and the *sortKey*)
- *value:* height coordinate on the value axis of this bar (this is the *mainValue*)

The container for storing multiple data points is QCPBarsDataContainer. It is a typedef for QCPDataContainer with QCPBarsData as the DataType template parameter. See the documentation there for an explanation regarding the data type's generic methods.

See also

QCPBarsDataContainer

17.616.2 Constructor & Destructor Documentation

17.616.2.1 QCPBarsData() [1/2]

```
QCPBarsData::QCPBarsData ( )
```

Constructs a bar data point with key and value set to zero.

17.616.2.2 QCPBarsData() [2/2]

```
QCPBarsData::QCPBarsData (
            double key,
            double value )
```

Constructs a bar data point with the specified *key* and *value*.

17.616.3 Member Function Documentation

17.616.3.1 fromSortKey()

```
static QCPBarsData QCPBarsData::fromSortKey (
            double sortKey )  [inline], [static]
```

Returns a data point with the specified *sortKey*. All other members are set to zero.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.616.3.2 mainKey()

```
double QCPBarsData::mainKey ( ) const  [inline]
```

Returns the *key* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.616.3.3 mainValue()

```
double QCPBarsData::mainValue ( ) const  [inline]
```

Returns the *value* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.616.3.4 sortKey()

```
double QCPBarsData::sortKey ( ) const  [inline]
```

Returns the *key* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.616.3.5 sortKeyIsMainKey()

```
static static bool QCPBarsData::sortKeyIsMainKey ( )  [inline], [static]
```

Since the member *key* is both the data point key coordinate and the data ordering parameter, this method returns true.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.616.3.6 valueRange()

```
QCPRange QCPBarsData::valueRange ( ) const  [inline]
```

Returns a QCPRange with both lower and upper boundary set to *value* of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.
The documentation for this class was generated from the following files:

17.617.1 Detailed Description

Groups multiple QCPBars together so they appear side by side.
When showing multiple QCPBars in one plot which have bars at identical keys, it may be desirable to have them appearing next to each other at each key. This is what adding the respective QCPBars plottables to a QCPBarsGroup achieves. (An alternative approach is to stack them on top of each other, see QCPBars::moveAbove.)

17.617.2 Usage

To add a QCPBars plottable to the group, create a new group and then add the respective bars intances:
Alternatively to appending to the group like shown above, you can also set the group on the QCPBars plottable via QCPBars::setBarsGroup.
The spacing between the bars can be configured via setSpacingType and setSpacing. The bars in this group appear in the plot in the order they were appended. To insert a bars plottable at a certain index position, or to reposition a bars plottable which is already in the group, use insert.
To remove specific bars from the group, use either remove or call QCPBars::setBarsGroup(0) on the respective bars plottable.
To clear the entire group, call clear, or simply delete the group.

17.617.3 Example

The image above is generated with the following code:

17.617.4 Member Enumeration Documentation

17.617.4.1 SpacingType

```
enum QCPBarsGroup::SpacingType
```

Defines the ways the spacing between bars in the group can be specified. Thus it defines what the number passed to setSpacing actually means.

See also

setSpacingType, setSpacing

Enumerator

stAbsolute	Bar spacing is in absolute pixels.
stAxisRectRatio	Bar spacing is given by a fraction of the axis rect size.
stPlotCoords	Bar spacing is in key coordinates and thus scales with the key axis range.

17.617.5 Constructor & Destructor Documentation

17.617.5.1 QCPBarsGroup()

```
QCPBarsGroup::QCPBarsGroup (
            QCustomPlot * parentPlot )  [explicit]
```

Constructs a new bars group for the specified QCustomPlot instance.

17.617.6 Member Function Documentation

17.617.6.1 append()

```
void QCPBarsGroup::append (
            QCPBars * bars )
```

Adds the specified *bars* plottable to this group. Alternatively, you can also use QCPBars::setBarsGroup on the *bars* instance.

See also

insert, remove

17.617.6.2 bars() [1/2]

```
QList< QCPBars * > QCPBarsGroup::bars ( ) const  [inline]
```

Returns all bars currently in this group.

See also

bars(int index)

17.617.6.3 bars() [2/2]

```
QCPBars * QCPBarsGroup::bars (
            int index ) const
```

Returns the QCPBars instance with the specified *index* in this group. If no such QCPBars exists, returns `nullptr`.

See also

bars(), size

17.617.6.4 clear()

```
void QCPBarsGroup::clear ( )
```

Removes all QCPBars plottables from this group.

See also

isEmpty

17.617.6.5 contains()

```
bool QCPBarsGroup::contains (
            QCPBars * bars ) const  [inline]
```

Returns whether the specified *bars* plottable is part of this group.

17.617.6.6 insert()

```
void QCPBarsGroup::insert (
            int i,
            QCPBars * bars )
```

Inserts the specified *bars* plottable into this group at the specified index position *i*. This gives you full control over the ordering of the bars.
bars may already be part of this group. In that case, *bars* is just moved to the new index position.

See also

append, remove

17.617.6.7 isEmpty()

```
bool QCPBarsGroup::isEmpty ( ) const  [inline]
```
Returns whether this bars group is empty.

See also

size

17.617.6.8 remove()

```
void QCPBarsGroup::remove (
            QCPBars * bars )
```
Removes the specified *bars* plottable from this group.

See also

contains, clear

17.617.6.9 setSpacing()

```
void QCPBarsGroup::setSpacing (
            double spacing )
```
Sets the spacing between adjacent bars. What the number passed as *spacing* actually means, is defined by the current SpacingType, which can be set with setSpacingType.

See also

setSpacingType

17.617.6.10 setSpacingType()

```
void QCPBarsGroup::setSpacingType (
            SpacingType spacingType )
```
Sets how the spacing between adjacent bars is interpreted. See SpacingType.
The actual spacing can then be specified with setSpacing.

See also

setSpacing

17.617.6.11 size()

```
int QCPBarsGroup::size ( ) const  [inline]
```
Returns the number of QCPBars plottables that are part of this group.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

- bool **mPeriodic**
- QVector< QRgb > **mColorBuffer**
- bool **mColorBufferInvalidated**

17.618.1 Detailed Description

Defines a color gradient for use with e.g. QCPColorMap.
This class describes a color gradient which can be used to encode data with color. For example, QCPColorMap and QCPColorScale have setGradient methods which take an instance of this class. Colors are set with setColorStopAt(double position, const QColor &color) with a *position* from 0 to 1. In between these defined color positions, the color will be interpolated linearly either in RGB or HSV space, see setColorInterpolation.
Alternatively, load one of the preset color gradients shown in the image below, with loadPreset, or by directly specifying the preset in the constructor.
Apart from red, green and blue components, the gradient also interpolates the alpha values of the configured color stops. This allows to display some portions of the data range as transparent in the plot.
How NaN values are interpreted can be configured with setNanHandling.
The constructor QCPColorGradient(GradientPreset preset) allows directly converting a GradientPreset to a QCPColorGradient. This means that you can directly pass GradientPreset to all the *setGradient* methods, e.g.:
The total number of levels used in the gradient can be set with setLevelCount. Whether the color gradient shall be applied periodically (wrapping around) to data values that lie outside the data range specified on the plottable instance can be controlled with setPeriodic.

17.618.2 Member Enumeration Documentation

17.618.2.1 ColorInterpolation

`enum QCPColorGradient::ColorInterpolation`
Defines the color spaces in which color interpolation between gradient stops can be performed.

See also

setColorInterpolation

Enumerator

ciRGB	Color channels red, green and blue are linearly interpolated.
ciHSV	Color channels hue, saturation and value are linearly interpolated (The hue is interpolated over the shortest angle distance)

17.618.2.2 GradientPreset

`enum QCPColorGradient::GradientPreset`
Defines the available presets that can be loaded with loadPreset. See the documentation there for an image of the presets.

Enumerator

gpGrayscale	Continuous lightness from black to white (suited for non-biased data representation)
gpHot	Continuous lightness from black over firey colors to white (suited for non-biased data representation)
gpCold	Continuous lightness from black over icey colors to white (suited for non-biased data representation)
gpNight	Continuous lightness from black over weak blueish colors to white (suited for non-biased data representation)
gpCandy	Blue over pink to white.
gpGeography	Colors suitable to represent different elevations on geographical maps.
gpIon	Half hue spectrum from black over purple to blue and finally green (creates banding illusion but allows more precise magnitude estimates)
gpThermal	Colors suitable for thermal imaging, ranging from dark blue over purple to orange, yellow and white.

Enumerator

gpPolar	Colors suitable to emphasize polarity around the center, with blue for negative, black in the middle and red for positive values.
gpSpectrum	An approximation of the visible light spectrum (creates banding illusion but allows more precise magnitude estimates)
gpJet	Hue variation similar to a spectrum, often used in numerical visualization (creates banding illusion but allows more precise magnitude estimates)
gpHues	Full hue cycle, with highest and lowest color red (suitable for periodic data, such as angles and phases, see setPeriodic)

17.618.2.3 NanHandling

`enum QCPColorGradient::NanHandling`

Defines how NaN data points shall appear in the plot.

See also

setNanHandling, setNanColor

Enumerator

nhNone	NaN data points are not explicitly handled and shouldn't occur in the data (this gives slight performance improvement)
nhLowestColor	NaN data points appear as the lowest color defined in this QCPColorGradient.
nhHighestColor	NaN data points appear as the highest color defined in this QCPColorGradient.
nhTransparent	NaN data points appear transparent.
nhNanColor	NaN data points appear as the color defined with setNanColor.

17.618.3 Constructor & Destructor Documentation

17.618.3.1 QCPColorGradient() [1/2]

```
QCPColorGradient::QCPColorGradient ( )
```

Constructs a new, empty QCPColorGradient with no predefined color stops. You can add own color stops with setColorStopAt.
The color level count is initialized to 350.

17.618.3.2 QCPColorGradient() [2/2]

```
QCPColorGradient::QCPColorGradient (
            GradientPreset preset )
```

Constructs a new QCPColorGradient initialized with the colors and color interpolation according to *preset*.
The color level count is initialized to 350.

17.618.4 Member Function Documentation

17.618.4.1 clearColorStops()

```
void QCPColorGradient::clearColorStops ( )
```

Clears all color stops.

See also

setColorStops, setColorStopAt

17.618.4.2 colorize() [1/2]

```
void QCPColorGradient::colorize (
            const double * data,
            const QCPRange & range,
            QRgb * scanLine,
            int n,
            int dataIndexFactor = 1,
            bool logarithmic = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
This method is used to quickly convert a *data* array to colors. The colors will be output in the array *scanLine*. Both *data* and *scanLine* must have the length *n* when passed to this function. The data range that shall be used for mapping the data value to the gradient is passed in *range*. *logarithmic* indicates whether the data values shall be mapped to colors logarithmically.
if *data* actually contains 2D-data linearized via `[row*columnCount + column]`, you can set *dataIndexFactor* to `columnCount` to convert a column instead of a row of the data array, in *scanLine*. *scanLine* will remain a regular (1D) array. This works because *data* is addressed `data[i*dataIndexFactor]`.
Use the overloaded method to additionally provide alpha map data.
The QRgb values that are placed in *scanLine* have their r, g, and b components premultiplied with alpha (see QImage::Format_ARGB32_Premultiplied).

17.618.4.3 colorize() [2/2]

```
void QCPColorGradient::colorize (
            const double * data,
            const unsigned char * alpha,
            const QCPRange & range,
            QRgb * scanLine,
            int n,
            int dataIndexFactor = 1,
            bool logarithmic = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Additionally to the other overload of colorize, this method takes the array *alpha*, which has the same size and structure as *data* and encodes the alpha information per data point.
The QRgb values that are placed in *scanLine* have their r, g and b components premultiplied with alpha (see QImage::Format_ARGB32_Premultiplied).

17.618.4.4 inverted()

```
QCPColorGradient QCPColorGradient::inverted ( ) const
```

Returns an inverted gradient. The inverted gradient has all properties as this QCPColorGradient, but the order of the color stops is inverted.

See also

setColorStops, setColorStopAt

17.618.4.5 loadPreset()

```
void QCPColorGradient::loadPreset (
            GradientPreset preset )
```

Clears the current color stops and loads the specified *preset*. A preset consists of predefined color stops and the corresponding color interpolation method.
The available presets are:

17.618.4.6 setColorInterpolation()

```
void QCPColorGradient::setColorInterpolation (
            QCPColorGradient::ColorInterpolation interpolation )
```

Sets whether the colors in between the configured color stops (see setColorStopAt) shall be interpolated linearly in RGB or in HSV color space.
For example, a sweep in RGB space from red to green will have a muddy brown intermediate color, whereas in HSV space the intermediate color is yellow.

17.618.4.7 setColorStopAt()

```
void QCPColorGradient::setColorStopAt (
            double position,
            const QColor & color )
```

Sets the *color* the gradient will have at the specified *position* (from 0 to 1). In between these color stops, the color is interpolated according to setColorInterpolation.

See also

setColorStops, clearColorStops

17.618.4.8 setColorStops()

```
void QCPColorGradient::setColorStops (
            const QMap< double, QColor > & colorStops )
```

Sets at which positions from 0 to 1 which color shall occur. The positions are the keys, the colors are the values of the passed QMap *colorStops*. In between these color stops, the color is interpolated according to setColorInterpolation.
A more convenient way to create a custom gradient may be to clear all color stops with clearColorStops (or creating a new, empty QCPColorGradient) and then adding them one by one with setColorStopAt.

See also

clearColorStops

17.618.4.9 setLevelCount()

```
void QCPColorGradient::setLevelCount (
            int n )
```

Sets the number of discretization levels of the color gradient to *n*. The default is 350 which is typically enough to create a smooth appearance. The minimum number of levels is 2.

17.618.4.10 setNanColor()

```
void QCPColorGradient::setNanColor (
            const QColor & color )
```

Sets the color that NaN data is represented by, if setNanHandling is set to ref nhNanColor.

See also

setNanHandling

17.618.4.11 setNanHandling()

```
void QCPColorGradient::setNanHandling (
            QCPColorGradient::NanHandling handling )
```

Sets how NaNs in the data are displayed in the plot.

See also

setNanColor

17.618.4.12 setPeriodic()

```
void QCPColorGradient::setPeriodic (
            bool enabled )
```

Sets whether data points that are outside the configured data range (e.g. QCPColorMap::setDataRange) are colored by periodically repeating the color gradient or whether they all have the same color, corresponding to the respective gradient boundary color.
As shown in the image above, gradients that have the same start and end color are especially suitable for a periodic gradient mapping, since they produce smooth color transitions throughout the color map. A preset that has this property is gpHues.
In practice, using periodic color gradients makes sense when the data corresponds to a periodic dimension, such as an angle or a phase. If this is not the case, the color encoding might become ambiguous, because multiple different data values are shown as the same color.

17.619.1 Detailed Description

A plottable representing a two-dimensional color map in a plot.
The data is stored in the class QCPColorMapData, which can be accessed via the data() method.
A color map has three dimensions to represent a data point: The *key* dimension, the *value* dimension and the *data* dimension. As with other plottables such as graphs, *key* and *value* correspond to two orthogonal axes on the QCustomPlot surface that you specify in the QCPColorMap constructor. The *data* dimension however is encoded as the color of the point at (*key*, *value*).
Set the number of points (or *cells*) in the key/value dimension via QCPColorMapData::setSize. The plot coordinate range over which these points will be displayed is specified via QCPColorMapData::setRange. The first cell will be centered on the lower range boundary and the last cell will be centered on the upper range boundary. The data can be set by either accessing the cells directly with QCPColorMapData::setCell or by addressing the cells via their plot coordinates with QCPColorMapData::setData. If possible, you should prefer setCell, since it doesn't need to do any coordinate transformation and thus performs a bit better.
The cell with index (0, 0) is at the bottom left, if the color map uses normal (i.e. not reversed) key and value axes.
To show the user which colors correspond to which *data* values, a QCPColorScale is typically placed to the right of the axis rect. See the documentation there for details on how to add and use a color scale.

17.619.2 Changing the appearance

Most important to the appearance is the color gradient, which can be specified via setGradient. See the documentation of QCPColorGradient for details on configuring a color gradient.
The *data* range that is mapped to the colors of the gradient can be specified with setDataRange. To make the data range encompass the whole data set minimum to maximum, call rescaleDataRange. If your data may contain NaN values, use QCPColorGradient::setNanHandling to define how they are displayed.

17.619.3 Transparency

Transparency in color maps can be achieved by two mechanisms. On one hand, you can specify alpha values for color stops of the QCPColorGradient, via the regular QColor interface. This will cause the color map data which gets mapped to colors around those color stops to appear with the accordingly interpolated transparency.
On the other hand you can also directly apply an alpha value to each cell independent of its data, by using the alpha map feature of QCPColorMapData. The relevant methods are QCPColorMapData::setAlpha, QCPColorMapData::fillAlpha and QCPColorMapData::clearAlpha().
The two transparencies will be joined together in the plot and otherwise not interfere with each other. They are mixed in a multiplicative matter, so an alpha of e.g. 50% (128/255) in both modes simultaneously, will result in a total transparency of 25% (64/255).

17.619.4 Usage

Like all data representing objects in QCustomPlot, the QCPColorMap is a plottable (QCPAbstractPlottable). So the plottable-interface of QCustomPlot applies (QCustomPlot::plottable, QCustomPlot::removePlottable, etc.)
Usually, you first create an instance:
which registers it with the QCustomPlot instance of the passed axes. Note that this QCustomPlot instance takes ownership of the plottable, so do not delete it manually but use QCustomPlot::removePlottable() instead. The newly created plottable can be modified, e.g.:

Note

The QCPColorMap always displays the data at equal key/value intervals, even if the key or value axis is set to a logarithmic scaling. If you want to use QCPColorMap with logarithmic axes, you shouldn't use the QCPColorMapData::setData method as it uses a linear transformation to determine the cell index. Rather directly access the cell index with QCPColorMapData::setCell.

17.619.5 Constructor & Destructor Documentation

17.619.5.1 QCPColorMap()

```
QCPColorMap::QCPColorMap (
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )  [explicit]
```

Constructs a color map with the specified *keyAxis* and *valueAxis*.
The created QCPColorMap is automatically registered with the QCustomPlot instance inferred from *keyAxis*. This QCustomPlot instance takes ownership of the QCPColorMap, so do not delete it manually but use QCustomPlot::removePlottable() instead.

17.619.6 Member Function Documentation

17.619.6.1 data()

```
QCPColorMapData * QCPColorMap::data ( ) const  [inline]
```

Returns a pointer to the internal data storage of type QCPColorMapData. Access this to modify data points (cells) and the color map key/value range.

See also

setData

17.619.6.2 dataRangeChanged

```
void QCPColorMap::dataRangeChanged (
            const QCPRange & newRange )  [signal]
```

This signal is emitted when the data range changes.

See also

setDataRange

17.619.6.3 dataScaleTypeChanged

```
void QCPColorMap::dataScaleTypeChanged (
            QCPAxis::ScaleType scaleType )  [signal]
```

This signal is emitted when the data scale type changes.

See also

setDataScaleType

17.619.6.4 draw()

```
void QCPColorMap::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.619.6.5 drawLegendIcon()

```
void QCPColorMap::drawLegendIcon (
            QCPPainter * painter,
            const QRectF & rect ) const  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.619.6.6 getKeyRange()

```
QCPRange QCPColorMap::getKeyRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth ) const  [virtual]
```

Returns the coordinate range that all data in this plottable span in the key axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSignDomain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getValueRange

Implements QCPAbstractPlottable.

17.619.6.7 getValueRange()

```
QCPRange QCPColorMap::getValueRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth,
            const QCPRange & inKeyRange = QCPRange() ) const  [virtual]
```

Returns the coordinate range that the data points in the specified key range (*inKeyRange*) span in the value axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSign↩ Domain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
If *inKeyRange* has both lower and upper bound set to zero (is equal to `QCPRange()`), all data points are considered, without any restriction on the keys.
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getKeyRange

Implements QCPAbstractPlottable.

17.619.6.8 gradientChanged

```
void QCPColorMap::gradientChanged (
            const QCPColorGradient & newGradient )  [signal]
```

This signal is emitted when the gradient changes.

See also

setGradient

17.619.6.9 rescaleDataRange()

```
void QCPColorMap::rescaleDataRange (
            bool recalculateDataBounds = false )
```

Sets the data range (setDataRange) to span the minimum and maximum values that occur in the current data set. This corresponds to the rescaleKeyAxis or rescaleValueAxis methods, only for the third data dimension of the color map.

The minimum and maximum values of the data set are buffered in the internal QCPColorMapData instance (data). As data is updated via its QCPColorMapData::setCell or QCPColorMapData::setData, the buffered minimum and maximum values are updated, too. For performance reasons, however, they are only updated in an expanding fashion. So the buffered maximum can only increase and the buffered minimum can only decrease. In consequence, changes to the data that actually lower the maximum of the data set (by overwriting the cell holding the current maximum with a smaller value), aren't recognized and the buffered maximum overestimates the true maximum of the data set. The same happens for the buffered minimum. To recalculate the true minimum and maximum by explicitly looking at each cell, the method QCPColorMapData::recalculateDataBounds can be used. For convenience, setting the parameter *recalculateDataBounds* calls this method before setting the data range to the buffered minimum and maximum.

See also

setDataRange

17.619.6.10 selectTest()

```
double QCPColorMap::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.

pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.

If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).

The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.

details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.

In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.

You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

See also

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Implements QCPAbstractPlottable.

17.619.6.11 setColorScale()

```
void QCPColorMap::setColorScale (
            QCPColorScale * colorScale )
```

Associates the color scale *colorScale* with this color map.

This means that both the color scale and the color map synchronize their gradient, data range and data scale type (setGradient, setDataRange, setDataScaleType). Multiple color maps can be associated with one single color scale. This causes the color maps to also synchronize those properties, via the mutual color scale.

This function causes the color map to adopt the current color gradient, data range and data scale type of *colorScale*. After this call, you may change these properties at either the color map or the color scale, and the setting will be applied to both.

Pass `nullptr` as *colorScale* to disconnect the color scale from this color map again.

17.619.6.12 setData()

```
void QCPColorMap::setData (
            QCPColorMapData * data,
            bool copy = false )
```

Replaces the current data with the provided *data*.
If *copy* is set to true, the *data* object will only be copied. if false, the color map takes ownership of the passed data and replaces the internal data pointer with it. This is significantly faster than copying for large datasets.

17.619.6.13 setDataRange()

```
void QCPColorMap::setDataRange (
            const QCPRange & dataRange )
```

Sets the data range of this color map to *dataRange*. The data range defines which data values are mapped to the color gradient.
To make the data range span the full range of the data set, use rescaleDataRange.

See also

QCPColorScale::setDataRange

17.619.6.14 setDataScaleType()

```
void QCPColorMap::setDataScaleType (
            QCPAxis::ScaleType scaleType )
```

Sets whether the data is correlated with the color gradient linearly or logarithmically.

See also

QCPColorScale::setDataScaleType

17.619.6.15 setGradient()

```
void QCPColorMap::setGradient (
            const QCPColorGradient & gradient )
```

Sets the color gradient that is used to represent the data. For more details on how to create an own gradient or use one of the preset gradients, see QCPColorGradient.
The colors defined by the gradient will be used to represent data values in the currently set data range, see setDataRange. Data points that are outside this data range will either be colored uniformly with the respective gradient boundary color, or the gradient will repeat, depending on QCPColorGradient::setPeriodic.

See also

QCPColorScale::setGradient

17.619.6.16 setInterpolate()

```
void QCPColorMap::setInterpolate (
            bool enabled )
```

Sets whether the color map image shall use bicubic interpolation when displaying the color map shrinked or expanded, and not at a 1:1 pixel-to-data scale.

17.619.6.17 setTightBoundary()

```
void QCPColorMap::setTightBoundary (
            bool enabled )
```

Sets whether the outer most data rows and columns are clipped to the specified key and value range (see QCPColorMapData::setKeyRange, QCPColorMapData::setValueRange).
if *enabled* is set to false, the data points at the border of the color map are drawn with the same width and height as all other data points. Since the data points are represented by rectangles of one color centered on the data coordinate, this means that the shown color map extends by half a data point over the specified key/value range in each direction.

17.619.6.18 updateLegendIcon()

```
void QCPColorMap::updateLegendIcon (
            Qt::TransformationMode transformMode = Qt::SmoothTransformation,
            const QSize & thumbSize = QSize(32, 18) )
```

Takes the current appearance of the color map and updates the legend icon, which is used to represent this color map in the legend (see QCPLegend).
The *transformMode* specifies whether the rescaling is done by a faster, low quality image scaling algorithm (Qt::FastTransformation) or by a slower, higher quality algorithm (Qt::SmoothTransformation).
The current color map appearance is scaled down to *thumbSize*. Ideally, this should be equal to the size of the legend icon (see QCPLegend::setIconSize). If it isn't exactly the configured legend icon size, the thumb will be rescaled during drawing of the legend item.

17.620.1 Detailed Description

Holds the two-dimensional data of a QCPColorMap plottable.
This class is a data storage for QCPColorMap. It holds a two-dimensional array, which QCPColorMap then displays as a 2D image in the plot, where the array values are represented by a color, depending on the value.
The size of the array can be controlled via setSize (or setKeySize, setValueSize). Which plot coordinates these cells correspond to can be configured with setRange (or setKeyRange, setValueRange).
The data cells can be accessed in two ways: They can be directly addressed by an integer index with setCell. This is the fastest method. Alternatively, they can be addressed by their plot coordinate with setData. plot coordinate to cell index transformations and vice versa are provided by the functions coordToCell and cellToCoord.
A QCPColorMapData also holds an on-demand two-dimensional array of alpha values which (if allocated) has the same size as the data map. It can be accessed via setAlpha, fillAlpha and clearAlpha. The memory for the alpha map is only allocated if needed, i.e. on the first call of setAlpha. clearAlpha restores full opacity and frees the alpha map.
This class also buffers the minimum and maximum values that are in the data set, to provide QCPColorMap::rescaleDataRange with the necessary information quickly. Setting a cell to a value that is greater than the current maximum increases this maximum to the new value. However, setting the cell that currently holds the maximum value to a smaller value doesn't decrease the maximum again, because finding the true new maximum would require going through the entire data array, which might be time consuming. The same holds for the data minimum. This functionality is

given by recalculateDataBounds, such that you can decide when it is sensible to find the true current minimum and maximum. The method QCPColorMap::rescaleDataRange offers a convenience parameter *recalculateDataBounds* which may be set to true to automatically call recalculateDataBounds internally.

17.620.2 Constructor & Destructor Documentation

17.620.2.1 QCPColorMapData() [1/2]

```
QCPColorMapData::QCPColorMapData (
            int keySize,
            int valueSize,
            const QCPRange & keyRange,
            const QCPRange & valueRange )
```

Constructs a new QCPColorMapData instance. The instance has *keySize* cells in the key direction and *valueSize* cells in the value direction. These cells will be displayed by the QCPColorMap at the coordinates *keyRange* and *valueRange*.

See also

setSize, setKeySize, setValueSize, setRange, setKeyRange, setValueRange

17.620.2.2 QCPColorMapData() [2/2]

```
QCPColorMapData::QCPColorMapData (
            const QCPColorMapData & other )
```

Constructs a new QCPColorMapData instance copying the data and range of *other*.

17.620.3 Member Function Documentation

17.620.3.1 alpha()

```
unsigned char QCPColorMapData::alpha (
            int keyIndex,
            int valueIndex )
```

Returns the alpha map value of the cell with the indices *keyIndex* and *valueIndex*.
If this color map data doesn't have an alpha map (because setAlpha was never called after creation or after a call to clearAlpha), returns 255, which corresponds to full opacity.

See also

setAlpha

17.620.3.2 cellToCoord()

```
void QCPColorMapData::cellToCoord (
            int keyIndex,
            int valueIndex,
            double * key,
            double * value ) const
```

Transforms cell indices given by *keyIndex* and *valueIndex* to cell indices of this QCPColorMapData instance. The resulting coordinates are returned via the output parameters *key* and *value*.
If you are only interested in a key or value coordinate, you may pass `nullptr` as *key* or *value*.

Note

The QCPColorMap always displays the data at equal key/value intervals, even if the key or value axis is set to a logarithmic scaling. If you want to use QCPColorMap with logarithmic axes, you shouldn't use the QCPColorMapData::cellToCoord method as it uses a linear transformation to determine the cell index.

See also

coordToCell, QCPAxis::pixelToCoord

17.620.3.3 clear()

```
void QCPColorMapData::clear ( )
```

Frees the internal data memory.
This is equivalent to calling setSize(0, 0).

17.620.3.4 clearAlpha()

```
void QCPColorMapData::clearAlpha ( )
```

Frees the internal alpha map. The color map will have full opacity again.

17.620.3.5 coordToCell()

```
void QCPColorMapData::coordToCell (
            double key,
            double value,
            int * keyIndex,
            int * valueIndex ) const
```

Transforms plot coordinates given by *key* and *value* to cell indices of this QCPColorMapData instance. The resulting cell indices are returned via the output parameters *keyIndex* and *valueIndex*.
The retrieved key/value cell indices can then be used for example with setCell.
If you are only interested in a key or value index, you may pass `nullptr` as *valueIndex* or *keyIndex*.

Note

The QCPColorMap always displays the data at equal key/value intervals, even if the key or value axis is set to a logarithmic scaling. If you want to use QCPColorMap with logarithmic axes, you shouldn't use the QCPColorMapData::coordToCell method as it uses a linear transformation to determine the cell index.

See also

cellToCoord, QCPAxis::coordToPixel

17.620.3.6 fill()

```
void QCPColorMapData::fill (
            double z )
```

Sets all cells to the value *z*.

17.620.3.7 fillAlpha()

```
void QCPColorMapData::fillAlpha (
            unsigned char alpha )
```

Sets the opacity of all color map cells to *alpha*. A value of 0 for *alpha* results in a fully transparent color map, and a value of 255 results in a fully opaque color map.
If you wish to restore opacity to 100% and free any used memory for the alpha map, rather use clearAlpha.

See also

setAlpha

17.620.3.8 isEmpty()

```
bool QCPColorMapData::isEmpty ( ) const  [inline]
```

Returns whether this instance carries no data. This is equivalent to having a size where at least one of the dimensions is 0 (see setSize).

17.620.3.9 operator=()

```
QCPColorMapData & QCPColorMapData::operator= (
            const QCPColorMapData & other )
```

Overwrites this color map data instance with the data stored in *other*. The alpha map state is transferred, too.

17.620.3.10 recalculateDataBounds()

```
void QCPColorMapData::recalculateDataBounds ( )
```

Goes through the data and updates the buffered minimum and maximum data values.
Calling this method is only advised if you are about to call QCPColorMap::rescaleDataRange and can not guarantee that the cells holding the maximum or minimum data haven't been overwritten with a smaller or larger value respectively, since the buffered maximum/minimum values have been updated the last time. Why this is the case is explained in the class description (QCPColorMapData).
Note that the method QCPColorMap::rescaleDataRange provides a parameter *recalculateDataBounds* for convenience. Setting this to true will call this method for you, before doing the rescale.

17.620.3.11 setAlpha()

```
void QCPColorMapData::setAlpha (
            int keyIndex,
            int valueIndex,
            unsigned char alpha )
```

Sets the alpha of the color map cell given by *keyIndex* and *valueIndex* to *alpha*. A value of 0 for *alpha* results in a fully transparent cell, and a value of 255 results in a fully opaque cell.
If an alpha map doesn't exist yet for this color map data, it will be created here. If you wish to restore full opacity and free any allocated memory of the alpha map, call clearAlpha.
Note that the cell-wise alpha which can be configured here is independent of any alpha configured in the color map's gradient (QCPColorGradient). If a cell is affected both by the cell-wise and gradient alpha, the alpha values will be blended accordingly during rendering of the color map.

See also

fillAlpha, clearAlpha

17.620.3.12 setCell()

```
void QCPColorMapData::setCell (
            int keyIndex,
            int valueIndex,
            double z )
```

Sets the data of the cell with indices *keyIndex* and *valueIndex* to *z*. The indices enumerate the cells starting from zero, up to the map's size-1 in the respective dimension (see setSize).
In the standard plot configuration (horizontal key axis and vertical value axis, both not range-reversed), the cell with indices (0, 0) is in the bottom left corner and the cell with indices (keySize-1, valueSize-1) is in the top right corner of the color map.

See also

setData, setSize

17.620.3.13 setData()

```
void QCPColorMapData::setData (
            double key,
            double value,
            double z )
```

Sets the data of the cell, which lies at the plot coordinates given by *key* and *value*, to *z*.

Note

The QCPColorMap always displays the data at equal key/value intervals, even if the key or value axis is set to a logarithmic scaling. If you want to use QCPColorMap with logarithmic axes, you shouldn't use the QCPColorMapData::setData method as it uses a linear transformation to determine the cell index. Rather directly access the cell index with QCPColorMapData::setCell.

See also

setCell, setRange

17.620.3.14 setKeyRange()

```
void QCPColorMapData::setKeyRange (
            const QCPRange & keyRange )
```

Sets the coordinate range the data shall be distributed over in the key dimension. Together with the value range, This defines the rectangular area covered by the color map in plot coordinates.
The outer cells will be centered on the range boundaries given to this function. For example, if the key size (setKeySize) is 3 and *keyRange* is set to `QCPRange(2, 3)` there will be cells centered on the key coordinates 2, 2.5 and 3.

See also

setRange, setValueRange, setSize

17.620.3.15 setKeySize()

```
void QCPColorMapData::setKeySize (
            int keySize )
```

Resizes the data array to have *keySize* cells in the key dimension.
The current data is discarded and the map cells are set to 0, unless the map had already the requested size.
Setting *keySize* to zero frees the internal data array and isEmpty returns true.

See also

setKeyRange, setSize, setValueSize

17.620.3.16 setRange()

```
void QCPColorMapData::setRange (
            const QCPRange & keyRange,
            const QCPRange & valueRange )
```

Sets the coordinate ranges the data shall be distributed over. This defines the rectangular area covered by the color map in plot coordinates.
The outer cells will be centered on the range boundaries given to this function. For example, if the key size (setKeySize) is 3 and *keyRange* is set to `QCPRange(2, 3)` there will be cells centered on the key coordinates 2, 2.5 and 3.

See also

setSize

17.620.3.17 setSize()

```
void QCPColorMapData::setSize (
            int keySize,
            int valueSize )
```

Resizes the data array to have *keySize* cells in the key dimension and *valueSize* cells in the value dimension.
The current data is discarded and the map cells are set to 0, unless the map had already the requested size.
Setting at least one of *keySize* or *valueSize* to zero frees the internal data array and isEmpty returns true.

See also

setRange, setKeySize, setValueSize

17.620.3.18 setValueRange()

```
void QCPColorMapData::setValueRange (
            const QCPRange & valueRange )
```

Sets the coordinate range the data shall be distributed over in the value dimension. Together with the key range, This defines the rectangular area covered by the color map in plot coordinates.
The outer cells will be centered on the range boundaries given to this function. For example, if the value size (setValueSize) is 3 and *valueRange* is set to `QCPRange(2, 3)` there will be cells centered on the value coordinates 2, 2.5 and 3.

See also

setRange, setKeyRange, setSize

17.620.3.19 setValueSize()

```
void QCPColorMapData::setValueSize (
            int valueSize )
```

Resizes the data array to have *valueSize* cells in the value dimension.
The current data is discarded and the map cells are set to 0, unless the map had already the requested size.
Setting *valueSize* to zero frees the internal data array and isEmpty returns true.

17.621.1 Detailed Description

A color scale for use with color coding data such as QCPColorMap.
This layout element can be placed on the plot to correlate a color gradient with data values. It is usually used in combination with one or multiple QCPColorMaps.
The color scale can be either horizontal or vertical, as shown in the image above. The orientation and the side where the numbers appear is controlled with setType.
Use QCPColorMap::setColorScale to connect a color map with a color scale. Once they are connected, they share their gradient, data range and data scale type (setGradient, setDataRange, setDataScaleType). Multiple color maps may be associated with a single color scale, to make them all synchronize these properties.
To have finer control over the number display and axis behaviour, you can directly access the axis. See the documentation of QCPAxis for details about configuring axes. For example, if you want to change the number of automatically generated ticks, call
Placing a color scale next to the main axis rect works like with any other layout element:
In this case we have placed it to the right of the default axis rect, so it wasn't necessary to call setType, since QCPAxis::atRight is already the default. The text next to the color scale can be set with setLabel.
For optimum appearance (like in the image above), it may be desirable to line up the axis rect and the borders of the color scale. Use a QCPMarginGroup to achieve this:
Color scales are initialized with a non-zero minimum top and bottom margin (setMinimumMargins), because vertical color scales are most common and the minimum top/bottom margin makes sure it keeps some distance to the top/bottom widget border. So if you change to a horizontal color scale by setting setType to QCPAxis::atBottom or QCPAxis::atTop, you might want to also change the minimum margins accordingly, e.g. `setMinimum↩Margins(QMargins(6, 0, 6, 0))`.

17.621.2 Constructor & Destructor Documentation

17.621.2.1 QCPColorScale()

```
QCPColorScale::QCPColorScale (
            QCustomPlot * parentPlot )  [explicit]
```

Constructs a new QCPColorScale.

17.621.3 Member Function Documentation

17.621.3.1 applyDefaultAntialiasingHint()

```
void QCPColorScale::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Reimplemented from QCPLayoutElement.

17.621.3.2 axis()

```
QCPAxis * QCPColorScale::axis ( ) const  [inline]
```

Returns the internal QCPAxis instance of this color scale. You can access it to alter the appearance and behaviour of the axis. QCPColorScale duplicates some properties in its interface for convenience. Those are setDataRange (QCPAxis::setRange), setDataScaleType (QCPAxis::setScaleType), and the method setLabel (QCPAxis::setLabel). As they each are connected, it does not matter whether you use the method on the QCPColorScale or on its QCPAxis.
If the type of the color scale is changed with setType, the axis returned by this method will change, too, to either the left, right, bottom or top axis, depending on which type was set.

17.621.3.3 colorMaps()

```
QList< QCPColorMap * > QCPColorScale::colorMaps ( ) const
```
Returns a list of all the color maps associated with this color scale.

17.621.3.4 dataRangeChanged

```
void QCPColorScale::dataRangeChanged (
            const QCPRange & newRange )  [signal]
```
This signal is emitted when the data range changes.

See also

setDataRange

17.621.3.5 dataScaleTypeChanged

```
void QCPColorScale::dataScaleTypeChanged (
            QCPAxis::ScaleType scaleType )  [signal]
```
This signal is emitted when the data scale type changes.

See also

setDataScaleType

17.621.3.6 gradientChanged

```
void QCPColorScale::gradientChanged (
            const QCPColorGradient & newGradient )  [signal]
```
This signal is emitted when the gradient changes.

See also

setGradient

17.621.3.7 mouseMoveEvent()

```
void QCPColorScale::mouseMoveEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```
This event gets called when the user moves the mouse while holding a mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.621.3.8 mousePressEvent()

```
void QCPColorScale::mousePressEvent (
            QMouseEvent * event,
            const QVariant & details )  [protected], [virtual]
```
This event gets called when the user presses a mouse button while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *details* contains layerable-specific details about the hit, which were generated in the previous call to selectTest.

For example, One-dimensional plottables like QCPGraph or QCPBars convey the clicked data point in the *details* parameter, as QCPDataSelection packed as QVariant. Multi-part objects convey the specific `SelectablePart` that was hit (e.g. QCPAxis::SelectablePart in the case of axes).
QCustomPlot uses an event propagation system that works the same as Qt's system. If your layerable doesn't reimplement the mousePressEvent or explicitly calls `event->ignore()` in its reimplementation, the event will be propagated to the next layerable in the stacking order.
Once a layerable has accepted the mousePressEvent, it is considered the mouse grabber and will receive all following calls to mouseMoveEvent or mouseReleaseEvent for this mouse interaction (a "mouse interaction" in this context ends with the release).
The default implementation does nothing except explicitly ignoring the event with `event->ignore()`.

See also

mouseMoveEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.621.3.9 mouseReleaseEvent()

```
void QCPColorScale::mouseReleaseEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user releases the mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseMoveEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.621.3.10 rescaleDataRange()

```
void QCPColorScale::rescaleDataRange (
            bool onlyVisibleMaps )
```

Changes the data range such that all color maps associated with this color scale are fully mapped to the gradient in the data dimension.

See also

setDataRange

17.621.3.11 setBarWidth()

```
void QCPColorScale::setBarWidth (
            int width )
```

Sets the width (or height, for horizontal color scales) the bar where the gradient is displayed will have.

17.621.3.12 setDataRange()

```
void QCPColorScale::setDataRange (
            const QCPRange & dataRange )
```

Sets the range spanned by the color gradient and that is shown by the axis in the color scale.
It is equivalent to calling QCPColorMap::setDataRange on any of the connected color maps. It is also equivalent to directly accessing the axis and setting its range with QCPAxis::setRange.

See also

setDataScaleType, setGradient, rescaleDataRange

17.621.3.13 setDataScaleType()

```
void QCPColorScale::setDataScaleType (
            QCPAxis::ScaleType scaleType )
```

Sets the scale type of the color scale, i.e. whether values are associated with colors linearly or logarithmically.
It is equivalent to calling QCPColorMap::setDataScaleType on any of the connected color maps. It is also equivalent to directly accessing the axis and setting its scale type with QCPAxis::setScaleType.
Note that this method controls the coordinate transformation. For logarithmic scales, you will likely also want to use a logarithmic tick spacing and labeling, which can be achieved by setting the color scale's axis ticker to an instance of QCPAxisTickerLog :
See the documentation of QCPAxisTickerLog about the details of logarithmic axis tick creation.

See also

setDataRange, setGradient

17.621.3.14 setGradient()

```
void QCPColorScale::setGradient (
            const QCPColorGradient & gradient )
```

Sets the color gradient that will be used to represent data values.
It is equivalent to calling QCPColorMap::setGradient on any of the connected color maps.

See also

setDataRange, setDataScaleType

17.621.3.15 setLabel()

```
void QCPColorScale::setLabel (
            const QString & str )
```

Sets the axis label of the color scale. This is equivalent to calling QCPAxis::setLabel on the internal axis.

17.621.3.16 setRangeDrag()

```
void QCPColorScale::setRangeDrag (
            bool enabled )
```

Sets whether the user can drag the data range (setDataRange).
Note that QCP::iRangeDrag must be in the QCustomPlot's interactions (QCustomPlot::setInteractions) to allow range dragging.

17.621.3.17 setRangeZoom()

```
void QCPColorScale::setRangeZoom (
            bool enabled )
```

Sets whether the user can zoom the data range (setDataRange) by scrolling the mouse wheel.
Note that QCP::iRangeZoom must be in the QCustomPlot's interactions (QCustomPlot::setInteractions) to allow range dragging.

17.621.3.18 setType()

```
void QCPColorScale::setType (
            QCPAxis::AxisType type )
```

Sets at which side of the color scale the axis is placed, and thus also its orientation.
Note that after setting *type* to a different value, the axis returned by axis() will be a different one. The new axis will adopt the following properties from the previous axis: The range, scale type, label and ticker (the latter will be shared and not copied).

17.621.3.19 update()

```
void QCPColorScale::update (
            UpdatePhase phase )  [virtual]
```

Updates the layout element and sub-elements. This function is automatically called before every replot by the parent layout element. It is called multiple times, once for every UpdatePhase. The phases are run through in the order of the enum values. For details about what happens at the different phases, see the documentation of UpdatePhase.
Layout elements that have child elements should call the update method of their child elements, and pass the current *phase* unchanged.
The default implementation executes the automatic margin mechanism in the upMargins phase. Subclasses should make sure to call the base class implementation.
Reimplemented from QCPLayoutElement.

17.621.3.20 wheelEvent()

```
void QCPColorScale::wheelEvent (
            QWheelEvent * event )  [protected], [virtual]
```

This event gets called when the user turns the mouse scroll wheel while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`.
The `event->angleDelta()` indicates how far the mouse wheel was turned, which is usually +/- 120 for single rotation steps. However, if the mouse wheel is turned rapidly, multiple steps may accumulate to one event, making the delta larger. On the other hand, if the wheel has very smooth steps or none at all, the delta may be smaller.
The default implementation does nothing.

17.622.1 Constructor & Destructor Documentation

17.622.1.1 QCPColorScaleAxisRectPrivate()

```
QCPColorScaleAxisRectPrivate::QCPColorScaleAxisRectPrivate (
            QCPColorScale * parentColorScale )  [explicit]
```

Creates a new instance, as a child of *parentColorScale*.

17.622.2 Member Function Documentation

17.622.2.1 calculateAutoMargin()

```
int QCPAxisRect::calculateAutoMargin (
            QCP::MarginSide side )  [protected], [virtual]
```

Reimplemented from QCPAxisRect.

17.622.2.2 draw()

```
void QCPColorScaleAxisRectPrivate::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Reimplemented from QCPAxisRect.

17.622.2.3 mouseMoveEvent()

```
void QCPAxisRect::mouseMoveEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user moves the mouse while holding a mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPAxisRect.

17.622.2.4 mousePressEvent()

```
void QCPAxisRect::mousePressEvent (
            QMouseEvent * event,
            const QVariant & details )  [protected], [virtual]
```

This event gets called when the user presses a mouse button while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *details* contains layerable-specific details about the hit, which were generated in the previous call to selectTest. For example, One-dimensional plottables like QCPGraph or QCPBars convey the clicked data point in the *details* parameter, as QCPDataSelection packed as QVariant. Multi-part objects convey the specific `SelectablePart` that was hit (e.g. QCPAxis::SelectablePart in the case of axes).
QCustomPlot uses an event propagation system that works the same as Qt's system. If your layerable doesn't reimplement the mousePressEvent or explicitly calls `event->ignore()` in its reimplementation, the event will be propagated to the next layerable in the stacking order.
Once a layerable has accepted the mousePressEvent, it is considered the mouse grabber and will receive all following calls to mouseMoveEvent or mouseReleaseEvent for this mouse interaction (a "mouse interaction" in this context ends with the release).
The default implementation does nothing except explicitly ignoring the event with `event->ignore()`.

See also

mouseMoveEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPAxisRect.

17.622.2.5 mouseReleaseEvent()

```
void QCPAxisRect::mouseReleaseEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user releases the mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseMoveEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPAxisRect.

17.622.2.6 update()

```
void QCPAxisRect::update (
            UpdatePhase phase )  [protected], [virtual]
```

This method is called automatically upon replot and doesn't need to be called by users of QCPAxisRect.
Calls the base class implementation to update the margins (see QCPLayoutElement::update), and finally passes the rect to the inset layout (insetLayout) and calls its QCPInsetLayout::update function.
\seebaseclassmethod
Reimplemented from QCPAxisRect.

17.622.2.7 wheelEvent()

```
void QCPAxisRect::wheelEvent (
            QWheelEvent * event )  [protected], [virtual]
```

This event gets called when the user turns the mouse scroll wheel while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`.
The `event->angleDelta()` indicates how far the mouse wheel was turned, which is usually +/- 120 for single rotation steps. However, if the mouse wheel is turned rapidly, multiple steps may accumulate to one event, making the delta larger. On the other hand, if the wheel has very smooth steps or none at all, the delta may be smaller.
The default implementation does nothing.

17.623.1 Detailed Description

A plottable representing a parametric curve in a plot.
Unlike QCPGraph, plottables of this type may have multiple points with the same key coordinate, so their visual representation can have *loops*. This is realized by introducing a third coordinate *t*, which defines the order of the points described by the other two coordinates *x* and *y*.
To plot data, assign it with the setData or addData functions. Alternatively, you can also access and modify the curve's data via the data method, which returns a pointer to the internal QCPCurveDataContainer.
Gaps in the curve can be created by adding data points with NaN as key and value (`qQNaN()` or `std::numeric_limits<double>::quiet_NaN()`) in between the two data points that shall be separated.

17.623.2 Changing the appearance

The appearance of the curve is determined by the pen and the brush (setPen, setBrush).

17.623.3 Usage

Like all data representing objects in QCustomPlot, the QCPCurve is a plottable (QCPAbstractPlottable). So the plottable-interface of QCustomPlot applies (QCustomPlot::plottable, QCustomPlot::removePlottable, etc.)
Usually, you first create an instance:
which registers it with the QCustomPlot instance of the passed axes. Note that this QCustomPlot instance takes ownership of the plottable, so do not delete it manually but use QCustomPlot::removePlottable() instead. The newly created plottable can be modified, e.g.:

17.623.4 Member Enumeration Documentation

17.623.4.1 LineStyle

```
enum QCPCurve::LineStyle
```

Defines how the curve's line is represented visually in the plot. The line is drawn with the current pen of the curve (setPen).

See also

setLineStyle

Enumerator

lsNone	No line is drawn between data points (e.g. only scatters)
lsLine	Data points are connected with a straight line.

17.623.5 Constructor & Destructor Documentation

17.623.5.1 QCPCurve()

```
QCPCurve::QCPCurve (
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )  [explicit]
```

Constructs a curve which uses *keyAxis* as its key axis ("x") and *valueAxis* as its value axis ("y"). *keyAxis* and *valueAxis* must reside in the same QCustomPlot instance and not have the same orientation. If either of these restrictions is violated, a corresponding message is printed to the debug output (qDebug), the construction is not aborted, though.

The created QCPCurve is automatically registered with the QCustomPlot instance inferred from *keyAxis*. This QCustomPlot instance takes ownership of the QCPCurve, so do not delete it manually but use QCustomPlot::removePlottable() instead.

17.623.6 Member Function Documentation

17.623.6.1 addData() [1/4]

```
void QCPCurve::addData (
            const QVector< double > & keys,
            const QVector< double > & values )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Adds the provided points in *keys* and *values* to the current data. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.

The t parameter of each data point will be set to the integer index of the respective key/value pair.

Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.623.6.2 addData() [2/4]

```
void QCPCurve::addData (
            const QVector< double > & t,
            const QVector< double > & keys,
            const QVector< double > & values,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Adds the provided points in *t*, *keys* and *values* to the current data. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.

If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.
Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.623.6.3 addData() [3/4]

```
void QCPCurve::addData (
            double key,
            double value )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds the provided data point as *key* and *value* to the current data.
The t parameter is generated automatically by increments of 1 for each point, starting at the highest t of previously existing data or 0, if the curve data is empty.
Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.623.6.4 addData() [4/4]

```
void QCPCurve::addData (
            double t,
            double key,
            double value )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. Adds the provided data point as *t*, *key* and *value* to the current data.
Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.623.6.5 data()

```
QSharedPointer< QCPCurveDataContainer > QCPCurve::data ( ) const  [inline]
```

Returns a shared pointer to the internal data storage of type QCPCurveDataContainer. You may use it to directly manipulate the data, which may be more convenient and faster than using the regular setData or addData methods.

17.623.6.6 draw()

```
void QCPCurve::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.623.6.7 drawLegendIcon()

```
void QCPCurve::drawLegendIcon (
            QCPPainter * painter,
            const QRectF & rect ) const  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.623.6.8 getKeyRange()

```
QCPRange QCPCurve::getKeyRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth ) const  [virtual]
```

Returns the coordinate range that all data in this plottable span in the key axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSignDomain* to QCP::sdBoth (default). *foundRange*

is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getValueRange

Implements QCPAbstractPlottable.

17.623.6.9 getValueRange()

```
QCPRange QCPCurve::getValueRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth,
            const QCPRange & inKeyRange = QCPRange() ) const  [virtual]
```

Returns the coordinate range that the data points in the specified key range (*inKeyRange*) span in the value axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSign↩ Domain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
If *inKeyRange* has both lower and upper bound set to zero (is equal to `QCPRange()`), all data points are considered, without any restriction on the keys.
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getKeyRange

Implements QCPAbstractPlottable.

17.623.6.10 selectTest()

```
double QCPCurve::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Implements a selectTest specific to this plottable's point geometry.
If *details* is not 0, it will be set to a QCPDataSelection, describing the closest data point to *pos*.
\seebaseclassmethod QCPAbstractPlottable::selectTest
Reimplemented from QCPAbstractPlottable1D< QCPCurveData >.

17.623.6.11 setData() [1/3]

```
void QCPCurve::setData (
            const QVector< double > & keys,
            const QVector< double > & values )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data with the provided points in *keys* and *values*. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.
The t parameter of each data point will be set to the integer index of the respective key/value pair.

See also

addData

17.623.6.12 setData() [2/3]

```
void QCPCurve::setData (
            const QVector< double > & t,
            const QVector< double > & keys,
            const QVector< double > & values,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data with the provided points in *t*, *keys* and *values*. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.
If you can guarantee that the passed data points are sorted by *t* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.

See also

addData

17.623.6.13 setData() [3/3]

```
void QCPCurve::setData (
            QSharedPointer< QCPCurveDataContainer > data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data container with the provided *data* container.
Since a QSharedPointer is used, multiple QCPCurves may share the same data container safely. Modifying the data in the container will then affect all curves that share the container. Sharing can be achieved by simply exchanging the data containers wrapped in shared pointers:
If you do not wish to share containers, but create a copy from an existing container, rather use the QCPDataContainer<DataType>::set method on the curve's data container directly:

See also

addData

17.623.6.14 setLineStyle()

```
void QCPCurve::setLineStyle (
            QCPCurve::LineStyle style )
```

Sets how the single data points are connected in the plot or how they are represented visually apart from the scatter symbol. For scatter-only plots, set *style* to lsNone and setScatterStyle to the desired scatter style.

See also

setScatterStyle

17.623.6.15 setScatterSkip()

```
void QCPCurve::setScatterSkip (
            int skip )
```

If scatters are displayed (scatter style not QCPScatterStyle::ssNone), *skip* number of scatter points are skipped/not drawn after every drawn scatter point.
This can be used to make the data appear sparser while for example still having a smooth line, and to improve performance for very high density plots.
If *skip* is set to 0 (default), all scatter points are drawn.

See also

setScatterStyle

17.623.6.16 setScatterStyle()

```
void QCPCurve::setScatterStyle (
            const QCPScatterStyle & style )
```

Sets the visual appearance of single data points in the plot. If set to QCPScatterStyle::ssNone, no scatter points are drawn (e.g. for line-only plots with appropriate line style).

See also

QCPScatterStyle, setLineStyle

- double sortKey () const
- double mainKey () const
- double mainValue () const
- QCPRange valueRange () const

Static Public Member Functions

- static QCPCurveData fromSortKey (double sortKey)
- static bool sortKeyIsMainKey ()

Public Attributes

- double **t**
- double **key**
- double **value**

17.624.1 Detailed Description

Holds the data of one single data point for QCPCurve.
The stored data is:

- *t:* the free ordering parameter of this curve point, like in the mathematical vector *(x(t), y(t))*. (This is the *sortKey*)
- *key:* coordinate on the key axis of this curve point (this is the *mainKey*)
- *value:* coordinate on the value axis of this curve point (this is the *mainValue*)

The container for storing multiple data points is QCPCurveDataContainer. It is a typedef for QCPDataContainer with QCPCurveData as the DataType template parameter. See the documentation there for an explanation regarding the data type's generic methods.

See also

QCPCurveDataContainer

17.624.2 Constructor & Destructor Documentation

17.624.2.1 QCPCurveData() [1/2]

```
QCPCurveData::QCPCurveData ( )
```
Constructs a curve data point with t, key and value set to zero.

17.624.2.2 QCPCurveData() [2/2]

```
QCPCurveData::QCPCurveData (
            double t,
            double key,
            double value )
```
Constructs a curve data point with the specified *t*, *key* and *value*.

17.624.3 Member Function Documentation

17.624.3.1 fromSortKey()

```
static QCPCurveData QCPCurveData::fromSortKey (
            double sortKey )  [inline], [static]
```
Returns a data point with the specified *sortKey* (assigned to the data point's *t* member). All other members are set to zero.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.624.3.2 mainKey()

```
double QCPCurveData::mainKey ( ) const  [inline]
```
Returns the *key* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.624.3.3 mainValue()

```
double QCPCurveData::mainValue ( ) const  [inline]
```
Returns the *value* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.624.3.4 sortKey()

```
double QCPCurveData::sortKey ( ) const  [inline]
```
Returns the *t* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.624.3.5 sortKeyIsMainKey()

```
static static bool QCPCurveData::sortKeyIsMainKey ( )  [inline], [static]
```
Since the member *key* is the data point key coordinate and the member *t* is the data ordering parameter, this method returns false.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.624.3.6 valueRange()

```
QCPRange QCPCurveData::valueRange ( ) const  [inline]
```
Returns a QCPRange with both lower and upper boundary set to *value* of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

The documentation for this class was generated from the following files:

17.625.1 Detailed Description

template<class DataType>
class QCPDataContainer< DataType >

The generic data container for one-dimensional plottables.
This class template provides a fast container for data storage of one-dimensional data. The data type is specified as template parameter (called *DataType* in the following) and must provide some methods as described in the next section.
The data is stored in a sorted fashion, which allows very quick lookups by the sorted key as well as retrieval of ranges (see findBegin, findEnd, keyRange) using binary search. The container uses a preallocation and a postallocation scheme, such that appending and prepending data (with respect to the sort key) is very fast and minimizes reallocations. If data is added which needs to be inserted between existing keys, the merge usually can be done quickly too, using the fact that existing data is always sorted. The user can further improve performance by specifying that added data is already itself sorted by key, if he can guarantee that this is the case (see for example add(const QVector<DataType> &data, bool alreadySorted)).
The data can be accessed with the provided const iterators (constBegin, constEnd). If it is necessary to alter existing data in-place, the non-const iterators can be used (begin, end). Changing data members that are not the sort key (for most data types called *key*) is safe from the container's perspective.
Great care must be taken however if the sort key is modified through the non-const iterators. For performance reasons, the iterators don't automatically cause a re-sorting upon their manipulation. It is thus the responsibility of the user to leave the container in a sorted state when finished with the data manipulation, before calling any other methods on the container. A complete re-sort (e.g. after finishing all sort key manipulation) can be done by calling sort. Failing to do so can not be detected by the container efficiently and will cause both rendering artifacts and potential data loss.
Implementing one-dimensional plottables that make use of a QCPDataContainer<T> is usually done by subclassing from QCPAbstractPlottable1D<T>, which introduces an according *mDataContainer* member and some convenience methods.

17.625.2 Requirements for the DataType template parameter

The template parameter `DataType` is the type of the stored data points. It must be trivially copyable and have the following public methods, preferably inline:

- `double sortKey() const`
  Returns the member variable of this data point that is the sort key, defining the ordering in the container. Often this variable is simply called *key*.

- `static DataType fromSortKey(double sortKey)`
  Returns a new instance of the data type initialized with its sort key set to *sortKey*.

- `static bool sortKeyIsMainKey()`
  Returns true if the sort key is equal to the main key (see method `mainKey` below). For most plottables this is the case. It is not the case for example for QCPCurve, which uses *t* as sort key and *key* as main key. This is the reason why QCPCurve unlike QCPGraph can display parametric curves with loops.

- `double mainKey() const`
  Returns the variable of this data point considered the main key. This is commonly the variable that is used as the coordinate of this data point on the key axis of the plottable. This method is used for example when determining the automatic axis rescaling of key axes (QCPAxis::rescale).

- `double mainValue() const`
  Returns the variable of this data point considered the main value. This is commonly the variable that is used as the coordinate of this data point on the value axis of the plottable.

- `QCPRange valueRange() const`
  Returns the range this data point spans in the value axis coordinate. If the data is single-valued (e.g. QCPGraphData), this is simply a range with both lower and upper set to the main data point value. However if the data points can represent multiple values at once (e.g QCPFinancialData with its *high*, *low*, *open* and *close* values at each *key*) this method should return the range those values span. This method is used for example when determining the automatic axis rescaling of value axes (QCPAxis::rescale).

17.625.3 Constructor & Destructor Documentation

17.625.3.1 QCPDataContainer()

```
template<class DataType >
QCPDataContainer< DataType >::QCPDataContainer ( )
```

Constructs a QCPDataContainer used for plottable classes that represent a series of key-sorted data

17.625.4 Member Function Documentation

17.625.4.1 add() [1/3]

```
template<class DataType >
void QCPDataContainer< DataType >::add (
            const DataType & data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds the provided single data point to the current data.

See also

remove

17.625.4.2 add() [2/3]

```
template<class DataType >
void QCPDataContainer< DataType >::add (
            const QCPDataContainer< DataType > & data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds the provided *data* to the current data in this container.

See also

set, remove

17.625.4.3 add() [3/3]

```
template<class DataType >
void QCPDataContainer< DataType >::add (
            const QVector< DataType > & data,
            bool alreadySorted = false )
```

Adds the provided data points in *data* to the current data.
If you can guarantee that the data points in *data* have ascending order with respect to the DataType's sort key, set *alreadySorted* to true to avoid an unnecessary sorting run.

See also

set, remove

17.625.4.4 at()

```
template<class DataType >
QCPDataContainer::const_iterator QCPDataContainer< DataType >::at (
            int index ) const  [inline]
```

Returns a const iterator to the element with the specified *index*. If *index* points beyond the available elements in this container, returns constEnd, i.e. an iterator past the last valid element.
You can use this method to easily obtain iterators from a QCPDataRange, see the data selection page for an example.

17.625.4.5 begin()

```
template<class DataType >
QCPDataContainer::iterator QCPDataContainer< DataType >::begin ( )  [inline]
```

Returns a non-const iterator to the first data point in this container.
You can manipulate the data points in-place through the non-const iterators, but great care must be taken when manipulating the sort key of a data point, see sort, or the detailed description of this class.

17.625.4.6 clear()

```
template<class DataType >
void QCPDataContainer< DataType >::clear ( )
```

Removes all data points.

See also

remove, removeAfter, removeBefore

17.625.4.7 constBegin()

```
template<class DataType >
QCPDataContainer::const_iterator QCPDataContainer< DataType >::constBegin ( ) const  [inline]
```

Returns a const iterator to the first data point in this container.

17.625.4.8 constEnd()

```
template<class DataType >
QCPDataContainer::const_iterator QCPDataContainer< DataType >::constEnd ( ) const  [inline]
```

Returns a const iterator to the element past the last data point in this container.

17.625.4.9 dataRange()

```
template<class DataType >
QCPDataRange QCPDataContainer< DataType >::dataRange ( ) const  [inline]
```

Returns a QCPDataRange encompassing the entire data set of this container. This means the begin index of the returned range is 0, and the end index is size.

17.625.4.10 end()

```
template<class DataType >
QCPDataContainer::iterator QCPDataContainer< DataType >::end ( )  [inline]
```

Returns a non-const iterator to the element past the last data point in this container.
You can manipulate the data points in-place through the non-const iterators, but great care must be taken when manipulating the sort key of a data point, see sort, or the detailed description of this class.

17.625.4.11 findBegin()

```
template<class DataType >
QCPDataContainer< DataType >::const_iterator QCPDataContainer< DataType >::findBegin (
            double sortKey,
            bool expandedRange = true ) const
```

Returns an iterator to the data point with a (sort-)key that is equal to, just below, or just above *sortKey*. If *expandedRange* is true, the data point just below *sortKey* will be considered, otherwise the one just above.
This can be used in conjunction with findEnd to iterate over data points within a given key range, including or excluding the bounding data points that are just beyond the specified range.
If *expandedRange* is true but there are no data points below *sortKey*, constBegin is returned.
If the container is empty, returns constEnd.

See also

findEnd, QCPPlottableInterface1D::findBegin

17.625.4.12 findEnd()

```
template<class DataType >
QCPDataContainer< DataType >::const_iterator QCPDataContainer< DataType >::findEnd (
            double sortKey,
            bool expandedRange = true ) const
```

Returns an iterator to the element after the data point with a (sort-)key that is equal to, just above or just below *sortKey*. If *expandedRange* is true, the data point just above *sortKey* will be considered, otherwise the one just below.
This can be used in conjunction with findBegin to iterate over data points within a given key range, including the bounding data points that are just below and above the specified range.
If *expandedRange* is true but there are no data points above *sortKey*, constEnd is returned.
If the container is empty, constEnd is returned.

See also

findBegin, QCPPlottableInterface1D::findEnd

17.625.4.13 isEmpty()

```
template<class DataType >
bool QCPDataContainer< DataType >::isEmpty ( ) const  [inline]
```

Returns whether this container holds no data points.

17.625.4.14 keyRange()

```
template<class DataType >
QCPRange QCPDataContainer< DataType >::keyRange (
            bool & foundRange,
            QCP::SignDomain signDomain = QCP::sdBoth )
```

Returns the range encompassed by the (main-)key coordinate of all data points. The output parameter *foundRange* indicates whether a sensible range was found. If this is false, you should not use the returned QCPRange (e.g. the data container is empty or all points have the same key).
Use *signDomain* to control which sign of the key coordinates should be considered. This is relevant e.g. for logarithmic plots which can mathematically only display one sign domain at a time.
If the DataType reports that its main key is equal to the sort key (*sortKeyIsMainKey*), as is the case for most plottables, this method uses this fact and finds the range very quickly.

See also

valueRange

17.625.4.15 limitIteratorsToDataRange()

```
template<class DataType >
void QCPDataContainer< DataType >::limitIteratorsToDataRange (
            const_iterator & begin,
            const_iterator & end,
            const QCPDataRange & dataRange ) const
```

Makes sure *begin* and *end* mark a data range that is both within the bounds of this data container's data, as well as within the specified *dataRange*. The initial range described by the passed iterators *begin* and *end* is never expanded, only contracted if necessary.
This function doesn't require for *dataRange* to be within the bounds of this data container's valid range.

17.625.4.16 remove() [1/2]

```
template<class DataType >
void QCPDataContainer< DataType >::remove (
            double sortKey )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Removes a single data point at *sortKey*. If the position is not known with absolute (binary) precision, consider using remove(double sortKeyFrom, double sortKeyTo) with a small fuzziness interval around the suspected position, depeding on the precision with which the (sort-)key is known.

See also

removeBefore, removeAfter, clear

17.625.4.17 remove() [2/2]

```
template<class DataType >
void QCPDataContainer< DataType >::remove (
            double sortKeyFrom,
            double sortKeyTo )
```

Removes all data points with (sort-)keys between *sortKeyFrom* and *sortKeyTo*. if *sortKeyFrom* is greater or equal to *sortKeyTo*, the function does nothing. To remove a single data point with known (sort-)key, use remove(double sortKey).

See also

removeBefore, removeAfter, clear

17.625.4.18 removeAfter()

```
template<class DataType >
void QCPDataContainer< DataType >::removeAfter (
            double sortKey )
```

Removes all data points with (sort-)keys greater than or equal to *sortKey*.

See also

removeBefore, remove, clear

17.625.4.19 removeBefore()

```
template<class DataType >
void QCPDataContainer< DataType >::removeBefore (
            double sortKey )
```

Removes all data points with (sort-)keys smaller than or equal to *sortKey*.

See also

removeAfter, remove, clear

17.625.4.20 set() [1/2]

```
template<class DataType >
void QCPDataContainer< DataType >::set (
            const QCPDataContainer< DataType > & data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data in this container with the provided *data*.

See also

add, remove

17.625.4.21 set() [2/2]

```
template<class DataType >
void QCPDataContainer< DataType >::set (
            const QVector< DataType > & data,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data in this container with the provided *data*
If you can guarantee that the data points in *data* have ascending order with respect to the DataType's sort key, set *alreadySorted* to true to avoid an unnecessary sorting run.

See also

add, remove

17.625.4.22 setAutoSqueeze()

```
template<class DataType >
void QCPDataContainer< DataType >::setAutoSqueeze (
            bool enabled )
```

Sets whether the container automatically decides when to release memory from its post- and preallocation pools when data points are removed. By default this is enabled and for typical applications shouldn't be changed.
If auto squeeze is disabled, you can manually decide when to release pre-/postallocation with squeeze.

17.625.4.23 size()

```
template<class DataType >
int QCPDataContainer< DataType >::size ( ) const  [inline]
```

Returns the number of data points in the container.

17.625.4.24 sort()

```
template<class DataType >
void QCPDataContainer< DataType >::sort ( )
```

Re-sorts all data points in the container by their sort key.
When setting, adding or removing points using the QCPDataContainer interface (set, add, remove, etc.), the container makes sure to always stay in a sorted state such that a full resort is never necessary. However, if you choose to directly manipulate the sort key on data points by accessing and modifying it through the non-const iterators (begin, end), it is your responsibility to bring the container back into a sorted state before any other methods are called on it. This can be achieved by calling this method immediately after finishing the sort key manipulation.

17.625.4.25 squeeze()

```
template<class DataType >
void QCPDataContainer< DataType >::squeeze (
```

```
            bool preAllocation = true,
            bool postAllocation = true )
```

Frees all unused memory that is currently in the preallocation and postallocation pools.
Note that QCPDataContainer automatically decides whether squeezing is necessary, if setAutoSqueeze is left enabled. It should thus not be necessary to use this method for typical applications.
The parameters *preAllocation* and *postAllocation* control whether pre- and/or post allocation should be freed, respectively.

17.625.4.26 valueRange()

```
template<class DataType >
QCPRange QCPDataContainer< DataType >::valueRange (
            bool & foundRange,
            QCP::SignDomain signDomain = QCP::sdBoth,
            const QCPRange & inKeyRange = QCPRange() )
```

Returns the range encompassed by the value coordinates of the data points in the specified key range (*inKeyRange*), using the full *DataType::valueRange* reported by the data points. The output parameter *foundRange* indicates whether a sensible range was found. If this is false, you should not use the returned QCPRange (e.g. the data container is empty or all points have the same value).
If *inKeyRange* has both lower and upper bound set to zero (is equal to `QCPRange()`), all data points are considered, without any restriction on the keys.
Use *signDomain* to control which sign of the value coordinates should be considered. This is relevant e.g. for logarithmic plots which can mathematically only display one sign domain at a time.

See also

keyRange

17.625.5 Friends And Related Symbol Documentation

17.625.5.1 qcpLessThanSortKey()

```
template<class DataType >
bool qcpLessThanSortKey (
            const DataType & a,
            const DataType & b )  [related]
```

Returns whether the sort key of *a* is less than the sort key of *b*.

17.626.1 Detailed Description

Describes a data range given by begin and end index.
QCPDataRange holds two integers describing the begin (setBegin) and end (setEnd) index of a contiguous set of data points. The *end* index corresponds to the data point just after the last data point of the data range, like in standard iterators.
Data Ranges are not bound to a certain plottable, thus they can be freely exchanged, created and modified. If a non-contiguous data set shall be described, the class QCPDataSelection is used, which holds and manages multiple instances of QCPDataRange. In most situations, QCPDataSelection is thus used.
Both QCPDataRange and QCPDataSelection offer convenience methods to work with them, e.g. bounded, expanded, intersects, intersection, adjusted, contains. Further, addition and subtraction operators (defined in QCPDataSelection) can be used to join/subtract data ranges and data selections (or mixtures), to retrieve a corresponding QCPDataSelection.
QCustomPlot's data selection mechanism is based on QCPDataSelection and QCPDataRange.

Note

> Do not confuse QCPDataRange with QCPRange. A QCPRange describes an interval in floating point plot coordinates, e.g. the current axis range.

17.626.2 Constructor & Destructor Documentation

17.626.2.1 QCPDataRange() [1/2]

```
QCPDataRange::QCPDataRange ( )
```

Creates an empty QCPDataRange, with begin and end set to 0.

17.626.2.2 QCPDataRange() [2/2]

```
QCPDataRange::QCPDataRange (
            int begin,
            int end )
```

Creates a QCPDataRange, initialized with the specified *begin* and *end*.
No checks or corrections are made to ensure the resulting range is valid (isValid).

17.626.3 Member Function Documentation

17.626.3.1 adjusted()

```
QCPDataRange QCPDataRange::adjusted (
            int changeBegin,
            int changeEnd ) const  [inline]
```

Returns a data range where *changeBegin* and *changeEnd* were added to the begin and end indices, respectively.

17.626.3.2 bounded()

```
QCPDataRange QCPDataRange::bounded (
            const QCPDataRange & other ) const
```

Returns a data range that matches this data range, except that parts exceeding *other* are excluded.
This method is very similar to intersection, with one distinction: If this range and the *other* range share no intersection, the returned data range will be empty with begin and end set to the respective boundary side of *other*, at which this range is residing. (intersection would just return a range with begin and end set to 0.)

17.626.3.3 contains()

```
bool QCPDataRange::contains (
            const QCPDataRange & other ) const
```

Returns whether all data points of *other* are also contained inside this data range.

See also

intersects

17.626.3.4 expanded()

```
QCPDataRange QCPDataRange::expanded (
            const QCPDataRange & other ) const
```

Returns a data range that contains both this data range as well as *other*.

17.626.3.5 intersection()

```
QCPDataRange QCPDataRange::intersection (
            const QCPDataRange & other ) const
```

Returns the data range which is contained in both this data range and *other*.
This method is very similar to bounded, with one distinction: If this range and the *other* range share no intersection, the returned data range will be empty with begin and end set to 0. (bounded would return a range with begin and end set to one of the boundaries of *other*, depending on which side this range is on.)

See also

QCPDataSelection::intersection

17.626.3.6 intersects()

```
bool QCPDataRange::intersects (
            const QCPDataRange & other ) const
```

Returns whether this data range and *other* share common data points.

See also

intersection, contains

17.626.3.7 isEmpty()

```
bool QCPDataRange::isEmpty ( ) const  [inline]
```

Returns whether this range is empty, i.e. whether its begin index equals its end index.

See also

size, length

17.626.3.8 isValid()

```
bool QCPDataRange::isValid ( ) const  [inline]
```

Returns whether this range is valid. A valid range has a begin index greater or equal to 0, and an end index greater or equal to the begin index.

Note

Invalid ranges should be avoided and are never the result of any of QCustomPlot's methods (unless they are themselves fed with invalid ranges). Do not pass invalid ranges to QCustomPlot's methods. The invalid range is not inherently prevented in QCPDataRange, to allow temporary invalid begin/end values while manipulating the range. An invalid range is not necessarily empty (isEmpty), since its length can be negative and thus non-zero.

17.626.3.9 length()

```
int QCPDataRange::length ( ) const  [inline]
```

Returns the number of data points described by this data range. Equivalent to size.

17.626.3.10 setBegin()

```
void QCPDataRange::setBegin (
            int begin )  [inline]
```

Sets the begin of this data range. The *begin* index points to the first data point that is part of the data range.
No checks or corrections are made to ensure the resulting range is valid (isValid).

See also

setEnd

17.626.3.11 setEnd()

```
void QCPDataRange::setEnd (
            int end )  [inline]
```

Sets the end of this data range. The *end* index points to the data point just after the last data point that is part of the data range.
No checks or corrections are made to ensure the resulting range is valid (isValid).

See also

setBegin

17.626.3.12 size()

```
int QCPDataRange::size ( ) const  [inline]
```

Returns the number of data points described by this data range. This is equal to the end index minus the begin index.

See also

length

17.626.4 Friends And Related Symbol Documentation

17.626.4.1 operator<<()

```
QDebug operator<< (
            QDebug d,
            const QCPDataRange & dataRange )  [related]
```

Prints *dataRange* in a human readable format to the qDebug output.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.627 QCPDataSelection Class Reference

Describes a data set by holding multiple QCPDataRange instances.

(Note that these are not member symbols.)

- QDebug operator<< (QDebug d, const QCPDataSelection &selection)

17.627.1 Detailed Description

Describes a data set by holding multiple QCPDataRange instances.
QCPDataSelection manages multiple instances of QCPDataRange in order to represent any (possibly disjoint) set of data selection.
The data selection can be modified with addition and subtraction operators which take QCPDataSelection and QCPDataRange instances, as well as methods such as addDataRange and clear. Read access is provided by dataRange, dataRanges, dataRangeCount, etc.
The method simplify is used to join directly adjacent or even overlapping QCPDataRange instances. QCPDataSelection automatically simplifies when using the addition/subtraction operators. The only case when simplify is left to the user, is when calling addDataRange, with the parameter *simplify* explicitly set to false. This is

useful if many data ranges will be added to the selection successively and the overhead for simplifying after each iteration shall be avoided. In this case, you should make sure to call simplify after completing the operation.
Use enforceType to bring the data selection into a state complying with the constraints for selections defined in QCP::SelectionType.
QCustomPlot's data selection mechanism is based on QCPDataSelection and QCPDataRange.

17.627.2 Iterating over a data selection

As an example, the following code snippet calculates the average value of a graph's data selection:

17.627.3 Constructor & Destructor Documentation

17.627.3.1 QCPDataSelection() [1/2]

```
QCPDataSelection::QCPDataSelection ( )  [explicit]
```

Creates an empty QCPDataSelection.

17.627.3.2 QCPDataSelection() [2/2]

```
QCPDataSelection::QCPDataSelection (
            const QCPDataRange & range )  [explicit]
```

Creates a QCPDataSelection containing the provided *range*.

17.627.4 Member Function Documentation

17.627.4.1 addDataRange()

```
void QCPDataSelection::addDataRange (
            const QCPDataRange & dataRange,
            bool simplify = true )
```

Adds the given *dataRange* to this data selection. This is equivalent to the += operator but allows disabling immediate simplification by setting *simplify* to false. This can improve performance if adding a very large amount of data ranges successively. In this case, make sure to call simplify manually, after the operation.

17.627.4.2 clear()

```
void QCPDataSelection::clear ( )
```

Removes all data ranges. The data selection then contains no data points.
isEmpty

17.627.4.3 contains()

```
bool QCPDataSelection::contains (
            const QCPDataSelection & other ) const
```

Returns true if the data selection *other* is contained entirely in this data selection, i.e. all data point indices that are in *other* are also in this data selection.

See also

QCPDataRange::contains

17.627.4.4 dataPointCount()

```
int QCPDataSelection::dataPointCount ( ) const
```

Returns the total number of data points contained in all data ranges that make up this data selection.

17.627.4.5 dataRange()

```
QCPDataRange QCPDataSelection::dataRange (
            int index = 0 ) const
```

Returns the data range with the specified *index*.
If the data selection is simplified (the usual state of the selection, see simplify), the ranges are sorted by ascending data point index.

See also

dataRangeCount

17.627.4.6 dataRangeCount()

```
int QCPDataSelection::dataRangeCount ( ) const  [inline]
```

Returns the number of ranges that make up the data selection. The ranges can be accessed by dataRange via their index.

See also

dataRange, dataPointCount

17.627.4.7 dataRanges()

```
QList< QCPDataRange > QCPDataSelection::dataRanges ( ) const  [inline]
```

Returns all data ranges that make up the data selection. If the data selection is simplified (the usual state of the selection, see simplify), the ranges are sorted by ascending data point index.

See also

dataRange

17.627.4.8 enforceType()

```
void QCPDataSelection::enforceType (
            QCP::SelectionType type )
```

Makes sure this data selection conforms to the specified *type* selection type. Before the type is enforced, simplify is called.
Depending on *type*, enforcing means adding new data points that were previously not part of the selection, or removing data points from the selection. If the current selection already conforms to *type*, the data selection is not changed.

See also

QCP::SelectionType

17.627.4.9 intersection() [1/2]

```
QCPDataSelection QCPDataSelection::intersection (
            const QCPDataRange & other ) const
```

Returns a data selection containing the points which are both in this data selection and in the data range *other*.
A common use case is to limit an unknown data selection to the valid range of a data container, using QCPDataContainer::dataRange as *other*. One can then safely iterate over the returned data selection without exceeding the data container's bounds.

17.627.4.10 intersection() [2/2]

```
QCPDataSelection QCPDataSelection::intersection (
            const QCPDataSelection & other ) const
```

Returns a data selection containing the points which are both in this data selection and in the data selection *other*.

17.627.4.11 inverse()

```
QCPDataSelection QCPDataSelection::inverse (
            const QCPDataRange & outerRange ) const
```

Returns a data selection which is the exact inverse of this data selection, with *outerRange* defining the base range on which to invert. If *outerRange* is smaller than the span of this data selection, it is expanded accordingly.
For example, this method can be used to retrieve all unselected segments by setting *outerRange* to the full data range of the plottable, and calling this method on a data selection holding the selected segments.

17.627.4.12 isEmpty()

```
bool QCPDataSelection::isEmpty ( ) const  [inline]
```

Returns true if there are no data ranges, and thus no data points, in this QCPDataSelection instance.

See also

dataRangeCount

17.627.4.13 operator+=() [1/2]

```
QCPDataSelection & QCPDataSelection::operator+= (
            const QCPDataRange & other )
```

Adds the data range *other* to this data selection, and then simplifies this data selection (see simplify).

17.627.4.14 operator+=() [2/2]

```
QCPDataSelection & QCPDataSelection::operator+= (
            const QCPDataSelection & other )
```

Adds the data selection of *other* to this data selection, and then simplifies this data selection (see simplify).

17.627.4.15 operator-=() [1/2]

```
QCPDataSelection & QCPDataSelection::operator-= (
            const QCPDataRange & other )
```

Removes all data point indices that are described by *other* from this data selection.

17.627.4.16 operator-=() [2/2]

```
QCPDataSelection & QCPDataSelection::operator-= (
            const QCPDataSelection & other )
```

Removes all data point indices that are described by *other* from this data selection.

17.627.4.17 operator==()

```
bool QCPDataSelection::operator== (
            const QCPDataSelection & other ) const
```

Returns true if this selection is identical (contains the same data ranges with the same begin and end indices) to *other*.
Note that both data selections must be in simplified state (the usual state of the selection, see simplify) for this operator to return correct results.

17.627.4.18 simplify()

```
void QCPDataSelection::simplify ( )
```

Sorts all data ranges by range begin index in ascending order, and then joins directly adjacent or overlapping ranges. This can reduce the number of individual data ranges in the selection, and prevents possible double-counting when iterating over the data points held by the data ranges.
This method is automatically called when using the addition/subtraction operators. The only case when simplify is left to the user, is when calling addDataRange, with the parameter *simplify* explicitly set to false.

17.627.4.19 span()

```
QCPDataRange QCPDataSelection::span ( ) const
```

Returns a QCPDataRange which spans the entire data selection, including possible intermediate segments which are not part of the original data selection.

17.627.5 Friends And Related Symbol Documentation

17.627.5.1 operator+ [1/4]

```
const QCPDataSelection operator+ (
            const QCPDataRange & a,
            const QCPDataRange & b )  [friend]
```

Return a QCPDataSelection with the data points in *a* joined with the data points in *b*. The resulting data selection is already simplified (see QCPDataSelection::simplify).

17.627.5.2 operator+ [2/4]

```
const QCPDataSelection operator+ (
            const QCPDataRange & a,
            const QCPDataSelection & b )  [friend]
```

Return a QCPDataSelection with the data points in *a* joined with the data points in *b*. The resulting data selection is already simplified (see QCPDataSelection::simplify).

17.627.5.3 operator+ [3/4]

```
const QCPDataSelection operator+ (
            const QCPDataSelection & a,
            const QCPDataRange & b )  [friend]
```

Return a QCPDataSelection with the data points in *a* joined with the data points in *b*. The resulting data selection is already simplified (see QCPDataSelection::simplify).

17.627.5.4 operator+ [4/4]

```
const QCPDataSelection operator+ (
            const QCPDataSelection & a,
            const QCPDataSelection & b )  [friend]
```

Return a QCPDataSelection with the data points in *a* joined with the data points in *b*. The resulting data selection is already simplified (see QCPDataSelection::simplify).

17.627.5.5 operator- [1/4]

```
const QCPDataSelection operator- (
            const QCPDataRange & a,
            const QCPDataRange & b )  [friend]
```

Return a QCPDataSelection with the data points which are in *a* but not in *b*.

17.627.5.6 operator- [2/4]

```
const QCPDataSelection operator- (
            const QCPDataRange & a,
            const QCPDataSelection & b )  [friend]
```

Return a QCPDataSelection with the data points which are in *a* but not in *b*.

17.627.5.7 operator- [3/4]

```
const QCPDataSelection operator- (
            const QCPDataSelection & a,
            const QCPDataRange & b )  [friend]
```

Return a QCPDataSelection with the data points which are in *a* but not in *b*.

17.627.5.8 operator- [4/4]

```
const QCPDataSelection operator- (
            const QCPDataSelection & a,
            const QCPDataSelection & b )  [friend]
```

Return a QCPDataSelection with the data points which are in *a* but not in *b*.

17.627.5.9 operator<<()

```
QDebug operator<< (
            QDebug d,
            const QCPDataSelection & selection )  [related]
```

Prints *selection* in a human readable format to the qDebug output.

17.628.1 Detailed Description

A plottable that adds a set of error bars to other plottables.
The QCPErrorBars plottable can be attached to other one-dimensional plottables (e.g. QCPGraph, QCPCurve, QCPBars, etc.) and equips them with error bars.
Use setDataPlottable to define for which plottable the QCPErrorBars shall display the error bars. The orientation of the error bars can be controlled with setErrorType.
By using setData, you can supply the actual error data, either as symmetric error or plus/minus asymmetric errors. QCPErrorBars only stores the error data. The absolute key/value position of each error bar will be adopted from the configured data plottable. The error data of the QCPErrorBars are associated one-to-one via their index to the data points of the data plottable. You can directly access and manipulate the error bar data via data.
Set either of the plus/minus errors to NaN (`qQNaN()` or `std::numeric_limits<double>::quiet_NaN()`) to not show the respective error bar on the data point at that index.

17.628.2 Changing the appearance

The appearance of the error bars is defined by the pen (setPen), and the width of the whiskers (setWhiskerWidth). Further, the error bar backbones may leave a gap around the data point center to prevent that error bars are drawn too close to or even through scatter points. This gap size can be controlled via setSymbolGap.

17.628.3 Member Enumeration Documentation

17.628.3.1 ErrorType

```
enum QCPErrorBars::ErrorType
```

Defines in which orientation the error bars shall appear. If your data needs both error dimensions, create two QCPErrorBars with different ErrorType.

See also

setErrorType

Enumerator

etKeyError	The errors are for the key dimension (bars appear parallel to the key axis)
etValueError	The errors are for the value dimension (bars appear parallel to the value axis)

17.628.4 Constructor & Destructor Documentation

17.628.4.1 QCPErrorBars()

```
QCPErrorBars::QCPErrorBars (
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )  [explicit]
```

Constructs an error bars plottable which uses *keyAxis* as its key axis ("x") and *valueAxis* as its value axis ("y"). *keyAxis* and *valueAxis* must reside in the same QCustomPlot instance and not have the same orientation. If either of these restrictions is violated, a corresponding message is printed to the debug output (qDebug), the construction is not aborted, though.
It is also important that the *keyAxis* and *valueAxis* are the same for the error bars plottable and the data plottable that the error bars shall be drawn on (setDataPlottable).
The created QCPErrorBars is automatically registered with the QCustomPlot instance inferred from *keyAxis*. This QCustomPlot instance takes ownership of the QCPErrorBars, so do not delete it manually but use QCustomPlot::removePlottable() instead.

17.628.5 Member Function Documentation

17.628.5.1 addData() [1/4]

```
void QCPErrorBars::addData (
            const QVector< double > & error )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds symmetrical error values as specified in *error*. The errors will be associated one-to-one by the data point index to the associated data plottable (setDataPlottable).
You can directly access and manipulate the error bar data via data.

See also

setData

17.628.5.2 addData() [2/4]

```
void QCPErrorBars::addData (
            const QVector< double > & errorMinus,
            const QVector< double > & errorPlus )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds asymmetrical errors as specified in *errorMinus* and *errorPlus*. The errors will be associated one-to-one by the data point index to the associated data plottable (setDataPlottable).
You can directly access and manipulate the error bar data via data.

See also

setData

17.628.5.3 addData() [3/4]

```
void QCPErrorBars::addData (
            double error )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds a single symmetrical error bar as specified in *error*. The errors will be associated one-to-one by the data point index to the associated data plottable (setDataPlottable).
You can directly access and manipulate the error bar data via data.

See also

setData

17.628.5.4 addData() [4/4]

```
void QCPErrorBars::addData (
            double errorMinus,
            double errorPlus )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds a single asymmetrical error bar as specified in *errorMinus* and *errorPlus*. The errors will be associated one-to-one by the data point index to the associated data plottable (setDataPlottable).
You can directly access and manipulate the error bar data via data.

See also

setData

17.628.5.5 data()

```
QSharedPointer< QCPErrorBarsDataContainer > QCPErrorBars::data ( ) const  [inline]
```

Returns a shared pointer to the internal data storage of type QCPErrorBarsDataContainer. You may use it to directly manipulate the error values, which may be more convenient and faster than using the regular setData methods.

17.628.5.6 dataCount()

```
int QCPErrorBars::dataCount ( ) const  [virtual]
```

Returns the number of data points of the plottable.
Implements QCPPlottableInterface1D.

17.628.5.7 dataMainKey()

```
double QCPErrorBars::dataMainKey (
            int index ) const  [virtual]
```

Returns the main key of the data point at the given *index*.
What the main key is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implements QCPPlottableInterface1D.

17.628.5.8 dataMainValue()

```
double QCPErrorBars::dataMainValue (
            int index ) const  [virtual]
```

Returns the main value of the data point at the given *index*.
What the main value is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implements QCPPlottableInterface1D.

17.628.5.9 dataPixelPosition()

```
QPointF QCPErrorBars::dataPixelPosition (
            int index ) const  [virtual]
```

Returns the pixel position on the widget surface at which the data point at the given *index* appears.
Usually this corresponds to the point of dataMainKey/ dataMainValue, in pixel coordinates. However, depending on the plottable, this might be a different apparent position than just a coord-to-pixel transform of those values. For example, QCPBars apparent data values can be shifted depending on their stacking, bar grouping or configured base value.
Implements QCPPlottableInterface1D.

17.628.5.10 dataSortKey()

```
double QCPErrorBars::dataSortKey (
            int index ) const  [virtual]
```

Returns the sort key of the data point at the given *index*.
What the sort key is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implements QCPPlottableInterface1D.

17.628.5.11 dataValueRange()

```
QCPRange QCPErrorBars::dataValueRange (
            int index ) const  [virtual]
```

Returns the value range of the data point at the given *index*.
What the value range is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implements QCPPlottableInterface1D.

17.628.5.12 draw()

```
void QCPErrorBars::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.628.5.13 drawLegendIcon()

```
void QCPErrorBars::drawLegendIcon (
            QCPPainter * painter,
            const QRectF & rect ) const  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.628.5.14 findBegin()

```
int QCPErrorBars::findBegin (
            double sortKey,
            bool expandedRange = true ) const  [virtual]
```

Returns the index of the data point with a (sort-)key that is equal to, just below, or just above *sortKey*. If *expanded↩ Range* is true, the data point just below *sortKey* will be considered, otherwise the one just above.
This can be used in conjunction with findEnd to iterate over data points within a given key range, including or excluding the bounding data points that are just beyond the specified range.
If *expandedRange* is true but there are no data points below *sortKey*, 0 is returned.
If the container is empty, returns 0 (in that case, findEnd will also return 0, so a loop using these methods will not iterate over the index 0).

See also

findEnd, QCPDataContainer::findBegin

Implements QCPPlottableInterface1D.

17.628.5.15 findEnd()

```
int QCPErrorBars::findEnd (
            double sortKey,
            bool expandedRange = true ) const  [virtual]
```

Returns the index one after the data point with a (sort-)key that is equal to, just above, or just below *sortKey*. If *expandedRange* is true, the data point just above *sortKey* will be considered, otherwise the one just below.
This can be used in conjunction with findBegin to iterate over data points within a given key range, including the bounding data points that are just below and above the specified range.
If *expandedRange* is true but there are no data points above *sortKey*, the index just above the highest data point is returned.
If the container is empty, returns 0.

See also

findBegin, QCPDataContainer::findEnd

Implements QCPPlottableInterface1D.

17.628.5.16 getKeyRange()

```
QCPRange QCPErrorBars::getKeyRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth ) const  [protected], [virtual]
```

Returns the coordinate range that all data in this plottable span in the key axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSignDomain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getValueRange

Implements QCPAbstractPlottable.

17.628.5.17 getValueRange()

```
QCPRange QCPErrorBars::getValueRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth,
            const QCPRange & inKeyRange = QCPRange() ) const  [protected], [virtual]
```

Returns the coordinate range that the data points in the specified key range (*inKeyRange*) span in the value axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSign↩ Domain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
If *inKeyRange* has both lower and upper bound set to zero (is equal to `QCPRange()`), all data points are considered, without any restriction on the keys.
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getKeyRange

Implements QCPAbstractPlottable.

17.628.5.18 interface1D()

```
virtual QCPPlottableInterface1D * QCPErrorBars::interface1D ( )  [inline], [virtual]
```

If this plottable is a one-dimensional plottable, i.e. it implements the QCPPlottableInterface1D, returns the *this* pointer with that type. Otherwise (e.g. in the case of a QCPColorMap) returns zero.
You can use this method to gain read access to data coordinates while holding a pointer to the abstract base class only.
Reimplemented from QCPAbstractPlottable.

17.628.5.19 selectTest()

```
double QCPErrorBars::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Implements a selectTest specific to this plottable's point geometry.
If *details* is not 0, it will be set to a QCPDataSelection, describing the closest data point to *pos*.
\seebaseclassmethod QCPAbstractPlottable::selectTest
Implements QCPAbstractPlottable.

17.628.5.20 selectTestRect()

```
QCPDataSelection QCPErrorBars::selectTestRect (
            const QRectF & rect,
            bool onlySelectable ) const  [virtual]
```

Returns a data selection containing all the data points of this plottable which are contained (or hit by) *rect*. This is used mainly in the selection rect interaction for data selection (data selection mechanism).
If *onlySelectable* is true, an empty QCPDataSelection is returned if this plottable is not selectable (i.e. if QCPAbstractPlottable::setSelectable is QCP::stNone).

Note

> *rect* must be a normalized rect (positive or zero width and height). This is especially important when using the rect of QCPSelectionRect::accepted, which is not necessarily normalized. Use `QRect::normalized()` when passing a rect which might not be normalized.

Implements QCPPlottableInterface1D.

17.628.5.21 setData() [1/3]

```
void QCPErrorBars::setData (
            const QVector< double > & error )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets symmetrical error values as specified in *error*. The errors will be associated one-to-one by the data point index to the associated data plottable (setDataPlottable).
You can directly access and manipulate the error bar data via data.

See also

> addData

17.628.5.22 setData() [2/3]

```
void QCPErrorBars::setData (
            const QVector< double > & errorMinus,
            const QVector< double > & errorPlus )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets asymmetrical errors as specified in *errorMinus* and *errorPlus*. The errors will be associated one-to-one by the data point index to the associated data plottable (setDataPlottable).
You can directly access and manipulate the error bar data via data.

See also

addData

17.628.5.23 setData() [3/3]

```
void QCPErrorBars::setData (
            QSharedPointer< QCPErrorBarsDataContainer > data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data container with the provided *data* container.
Since a QSharedPointer is used, multiple QCPErrorBars instances may share the same data container safely. Modifying the data in the container will then affect all QCPErrorBars instances that share the container. Sharing can be achieved by simply exchanging the data containers wrapped in shared pointers:
If you do not wish to share containers, but create a copy from an existing container, assign the data containers directly:
(This uses different notation compared with other plottables, because the QCPErrorBars uses a `QVector<QCPErrorBarsData>` as its data container, instead of a QCPDataContainer.)

See also

addData

17.628.5.24 setDataPlottable()

```
void QCPErrorBars::setDataPlottable (
            QCPAbstractPlottable * plottable )
```

Sets the data plottable to which the error bars will be applied. The error values specified e.g. via setData will be associated one-to-one by the data point index to the data points of *plottable*. This means that the error bars will adopt the key/value coordinates of the data point with the same index.
The passed *plottable* must be a one-dimensional plottable, i.e. it must implement the QCPPlottableInterface1D. Further, it must not be a QCPErrorBars instance itself. If either of these restrictions is violated, a corresponding qDebug output is generated, and the data plottable of this QCPErrorBars instance is set to zero.
For proper display, care must also be taken that the key and value axes of the *plottable* match those configured for this QCPErrorBars instance.

17.628.5.25 setErrorType()

```
void QCPErrorBars::setErrorType (
            ErrorType type )
```

Sets in which orientation the error bars shall appear on the data points. If your data needs both error dimensions, create two QCPErrorBars with different *type*.

17.628.5.26 setSymbolGap()

```
void QCPErrorBars::setSymbolGap (
            double pixels )
```

Sets the gap diameter around the data points that will be left out when drawing the error bar backbones. This gap prevents that error bars are drawn too close to or even through scatter points.

17.628.5.27 setWhiskerWidth()

```
void QCPErrorBars::setWhiskerWidth (
            double pixels )
```

Sets the width of the whiskers (the short bars at the end of the actual error bar backbones) to *pixels*.

17.628.5.28 sortKeyIsMainKey()

```
bool QCPErrorBars::sortKeyIsMainKey ( ) const  [virtual]
```

Returns whether the sort key (dataSortKey) is identical to the main key (dataMainKey).
What the sort and main keys are, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implements QCPPlottableInterface1D.

- applications/gui/genesys/qcustomplot.cpp

17.629 QCPErrorBarsData Class Reference

Holds the data of one single error bar for QCPErrorBars.

Public Member Functions

- QCPErrorBarsData ()
- QCPErrorBarsData (double error)
- QCPErrorBarsData (double errorMinus, double errorPlus)

Public Attributes

- double **errorMinus**
- double **errorPlus**

17.629.1 Detailed Description

Holds the data of one single error bar for QCPErrorBars.
The stored data is:

- *errorMinus:* how much the error bar extends towards negative coordinates from the data point position
- *errorPlus:* how much the error bar extends towards positive coordinates from the data point position

The container for storing the error bar information is QCPErrorBarsDataContainer. It is a typedef for `QVector<QCPErrorBarsData>`.

QCPErrorBarsDataContainer

17.629.2 Constructor & Destructor Documentation

17.629.2.1 QCPErrorBarsData() [1/3]

```
QCPErrorBarsData::QCPErrorBarsData ( )
```

Constructs an error bar with errors set to zero.

17.629.2.2 QCPErrorBarsData() [2/3]

```
QCPErrorBarsData::QCPErrorBarsData (
            double error )  [explicit]
```

Constructs an error bar with equal *error* in both negative and positive direction.

17.629.2.3 QCPErrorBarsData() [3/3]

```
QCPErrorBarsData::QCPErrorBarsData (
            double errorMinus,
            double errorPlus )
```

Constructs an error bar with negative and positive errors set to *errorMinus* and *errorPlus*, respectively.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.630.1 Detailed Description

A plottable representing a financial stock chart.
This plottable represents time series data binned to certain intervals, mainly used for stock charts. The two common representations OHLC (Open-High-Low-Close) bars and Candlesticks can be set via setChartStyle.
The data is passed via setData as a set of open/high/low/close values at certain keys (typically times). This means the data must be already binned appropriately. If data is only available as a series of values (e.g. *price* against *time*), you can use the static convenience function timeSeriesToOhlc to generate binned OHLC-data which can then be passed to setData.
The width of the OHLC bars/candlesticks can be controlled with setWidth and setWidthType. A typical choice is to set the width type to wtPlotCoords (the default) and the width to (or slightly less than) one time bin interval width.

17.630.2 Changing the appearance

Charts can be either single- or two-colored (setTwoColored). If set to be single-colored, lines are drawn with the plottable's pen (setPen) and fills with the brush (setBrush).
If set to two-colored, positive changes of the value during an interval (*close* >= *open*) are represented with a different pen and brush than negative changes (*close* < *open*). These can be configured with setPenPositive, setPenNegative, setBrushPositive, and setBrushNegative. In two-colored mode, the normal plottable pen/brush is ignored. Upon selection however, the normal selected pen/brush (provided by the selectionDecorator) is used, irrespective of whether the chart is single- or two-colored.

17.630.3 Usage

Like all data representing objects in QCustomPlot, the QCPFinancial is a plottable (QCPAbstractPlottable). So the plottable-interface of QCustomPlot applies (QCustomPlot::plottable, QCustomPlot::removePlottable, etc.)
Usually, you first create an instance:
which registers it with the QCustomPlot instance of the passed axes. Note that this QCustomPlot instance takes ownership of the plottable, so do not delete it manually but use QCustomPlot::removePlottable() instead. The newly created plottable can be modified, e.g.:
Here we have used the static helper method timeSeriesToOhlc, to turn a time-price data series into a 24-hour binned open-high-low-close data series as QCPFinancial uses.

17.630.4 Member Enumeration Documentation

17.630.4.1 ChartStyle

`enum QCPFinancial::ChartStyle`
Defines the possible representations of OHLC data in the plot.

See also

setChartStyle

Enumerator

csOhlc	Open-High-Low-Close bar representation.
csCandlestick	Candlestick representation.

17.630.4.2 WidthType

```
enum QCPFinancial::WidthType
```

Defines the ways the width of the financial bar can be specified. Thus it defines what the number passed to setWidth actually means.

See also

setWidthType, setWidth

Enumerator

wtAbsolute	width is in absolute pixels
wtAxisRectRatio	width is given by a fraction of the axis rect size
wtPlotCoords	width is in key coordinates and thus scales with the key axis range

17.630.5 Constructor & Destructor Documentation

17.630.5.1 QCPFinancial()

```
QCPFinancial::QCPFinancial (
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )  [explicit]
```

Constructs a financial chart which uses *keyAxis* as its key axis ("x") and *valueAxis* as its value axis ("y"). *keyAxis* and *valueAxis* must reside in the same QCustomPlot instance and not have the same orientation. If either of these restrictions is violated, a corresponding message is printed to the debug output (qDebug), the construction is not aborted, though.

The created QCPFinancial is automatically registered with the QCustomPlot instance inferred from *key*↩ *Axis*. This QCustomPlot instance takes ownership of the QCPFinancial, so do not delete it manually but use QCustomPlot::removePlottable() instead.

17.630.6 Member Function Documentation

17.630.6.1 addData() [1/2]

```
void QCPFinancial::addData (
            const QVector< double > & keys,
            const QVector< double > & open,
            const QVector< double > & high,
            const QVector< double > & low,
            const QVector< double > & close,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Adds the provided points in *keys*, *open*, *high*, *low* and *close* to the current data. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.

If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.

Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

See also

timeSeriesToOhlc

17.630.6.2 addData() [2/2]

```
void QCPFinancial::addData (
            double key,
```

```
            double open,
            double high,
            double low,
            double close )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds the provided data point as *key*, *open*, *high*, *low* and *close* to the current data.
Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

See also

timeSeriesToOhlc

17.630.6.3 data()

```
QCPFinancialDataContainer * QCPFinancial::data ( ) const  [inline]
```

Returns a pointer to the internal data storage of type QCPFinancialDataContainer. You may use it to directly manipulate the data, which may be more convenient and faster than using the regular setData or addData methods, in certain situations.

17.630.6.4 draw()

```
void QCPFinancial::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.630.6.5 drawLegendIcon()

```
void QCPFinancial::drawLegendIcon (
            QCPPainter * painter,
            const QRectF & rect ) const  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.630.6.6 getKeyRange()

```
QCPRange QCPFinancial::getKeyRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth ) const  [virtual]
```

Returns the coordinate range that all data in this plottable span in the key axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSignDomain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getValueRange

Implements QCPAbstractPlottable.

17.630.6.7 getValueRange()

```
QCPRange QCPFinancial::getValueRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth,
            const QCPRange & inKeyRange = QCPRange() ) const  [virtual]
```

Returns the coordinate range that the data points in the specified key range (*inKeyRange*) span in the value axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSign↩ Domain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
If *inKeyRange* has both lower and upper bound set to zero (is equal to `QCPRange()`), all data points are considered, without any restriction on the keys.
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getKeyRange

Implements QCPAbstractPlottable.

17.630.6.8 selectTest()

```
double QCPFinancial::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Implements a selectTest specific to this plottable's point geometry.
If *details* is not 0, it will be set to a QCPDataSelection, describing the closest data point to *pos*.
\seebaseclassmethod QCPAbstractPlottable::selectTest
Reimplemented from QCPAbstractPlottable1D< QCPFinancialData >.

17.630.6.9 selectTestRect()

```
QCPDataSelection QCPFinancial::selectTestRect (
            const QRectF & rect,
            bool onlySelectable ) const  [virtual]
```

Returns a data selection containing all the data points of this plottable which are contained (or hit by) *rect*. This is used mainly in the selection rect interaction for data selection (data selection mechanism).
If *onlySelectable* is true, an empty QCPDataSelection is returned if this plottable is not selectable (i.e. if QCPAbstractPlottable::setSelectable is QCP::stNone).

Note

rect must be a normalized rect (positive or zero width and height). This is especially important when using the rect of QCPSelectionRect::accepted, which is not necessarily normalized. Use `QRect::normalized()` when passing a rect which might not be normalized.

Reimplemented from QCPAbstractPlottable1D< QCPFinancialData >.

17.630.6.10 setBrushNegative()

```
void QCPFinancial::setBrushNegative (
            const QBrush & brush )
```

If setTwoColored is set to true, this function controls the brush that is used to draw fills of data points with a negative trend (i.e. bars/candlesticks with close < open).
If *twoColored* is false, the normal plottable's pen and brush are used (setPen, setBrush).

See also

setBrushPositive, setPenNegative, setPenPositive

17.630.6.11 setBrushPositive()

```
void QCPFinancial::setBrushPositive (
            const QBrush & brush )
```

If setTwoColored is set to true, this function controls the brush that is used to draw fills of data points with a positive trend (i.e. bars/candlesticks with close >= open).
If *twoColored* is false, the normal plottable's pen and brush are used (setPen, setBrush).

See also

setBrushNegative, setPenPositive, setPenNegative

17.630.6.12 setChartStyle()

```
void QCPFinancial::setChartStyle (
            QCPFinancial::ChartStyle style )
```

Sets which representation style shall be used to display the OHLC data.

17.630.6.13 setData() [1/2]

```
void QCPFinancial::setData (
            const QVector< double > & keys,
            const QVector< double > & open,
            const QVector< double > & high,
            const QVector< double > & low,
            const QVector< double > & close,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data with the provided points in *keys*, *open*, *high*, *low* and *close*. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.
If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.

addData, timeSeriesToOhlc

17.630.6.14 setData() [2/2]

```
void QCPFinancial::setData (
            QSharedPointer< QCPFinancialDataContainer > data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data container with the provided *data* container.
Since a QSharedPointer is used, multiple QCPFinancials may share the same data container safely. Modifying the data in the container will then affect all financials that share the container. Sharing can be achieved by simply exchanging the data containers wrapped in shared pointers:
If you do not wish to share containers, but create a copy from an existing container, rather use the QCPDataContainer<DataType>::set method on the financial's data container directly:

addData, timeSeriesToOhlc

17.630.6.15 setPenNegative()

```
void QCPFinancial::setPenNegative (
            const QPen & pen )
```

If setTwoColored is set to true, this function controls the pen that is used to draw outlines of data points with a negative trend (i.e. bars/candlesticks with close < open).
If *twoColored* is false, the normal plottable's pen and brush are used (setPen, setBrush).

See also

setPenPositive, setBrushNegative, setBrushPositive

17.630.6.16 setPenPositive()

```
void QCPFinancial::setPenPositive (
            const QPen & pen )
```

If setTwoColored is set to true, this function controls the pen that is used to draw outlines of data points with a positive trend (i.e. bars/candlesticks with close >= open).
If *twoColored* is false, the normal plottable's pen and brush are used (setPen, setBrush).

See also

setPenNegative, setBrushPositive, setBrushNegative

17.630.6.17 setTwoColored()

```
void QCPFinancial::setTwoColored (
            bool twoColored )
```

Sets whether this chart shall contrast positive from negative trends per data point by using two separate colors to draw the respective bars/candlesticks.
If *twoColored* is false, the normal plottable's pen and brush are used (setPen, setBrush).

See also

setPenPositive, setPenNegative, setBrushPositive, setBrushNegative

17.630.6.18 setWidth()

```
void QCPFinancial::setWidth (
            double width )
```

Sets the width of the individual bars/candlesticks to *width* in plot key coordinates.
A typical choice is to set it to (or slightly less than) one bin interval width.

17.630.6.19 setWidthType()

```
void QCPFinancial::setWidthType (
            QCPFinancial::WidthType widthType )
```

Sets how the width of the financial bars is defined. See the documentation of WidthType for an explanation of the possible values for *widthType*.
The default value is wtPlotCoords.

See also

setWidth

17.630.6.20 timeSeriesToOhlc()

```
QCPFinancialDataContainer QCPFinancial::timeSeriesToOhlc (
            const QVector< double > & time,
            const QVector< double > & value,
            double timeBinSize,
            double timeBinOffset = 0 )  [static]
```

A convenience function that converts time series data (*value* against *time*) to OHLC binned data points. The return value can then be passed on to QCPFinancialDataContainer::set(const QCPFinancialDataContainer&).
The size of the bins can be controlled with *timeBinSize* in the same units as *time* is given. For example, if the unit of *time* is seconds and single OHLC/Candlesticks should span an hour each, set *timeBinSize* to 3600.
timeBinOffset allows to control precisely at what *time* coordinate a bin should start. The value passed as *timeBinOffset* doesn't need to be in the range encompassed by the *time* keys. It merely defines the mathematical offset/phase of the bins that will be used to process the data.

17.631 QCPFinancialData Class Reference

Holds the data of one single data point for QCPFinancial.

Public Member Functions

- QCPFinancialData ()
- QCPFinancialData (double key, double open, double high, double low, double close)
- double sortKey () const
- double mainKey () const
- double mainValue () const
- QCPRange valueRange () const

Static Public Member Functions

- static QCPFinancialData fromSortKey (double sortKey)
- static bool sortKeyIsMainKey ()

Public Attributes

- double **key**
- double **open**
- double **high**
- double **low**
- double **close**

17.631.1 Detailed Description

Holds the data of one single data point for QCPFinancial.
The stored data is:

- *key:* coordinate on the key axis of this data point (this is the *mainKey* and the *sortKey*)
- *open:* The opening value at the data point (this is the *mainValue*)
- *high:* The high/maximum value at the data point
- *low:* The low/minimum value at the data point
- *close:* The closing value at the data point

The container for storing multiple data points is QCPFinancialDataContainer. It is a typedef for QCPDataContainer with QCPFinancialData as the DataType template parameter. See the documentation there for an explanation regarding the data type's generic methods.

QCPFinancialDataContainer

17.631.2 Constructor & Destructor Documentation

17.631.2.1 QCPFinancialData() [1/2]

`QCPFinancialData::QCPFinancialData ( )`
Constructs a data point with key and all values set to zero.

17.631.2.2 QCPFinancialData() [2/2]

```
QCPFinancialData::QCPFinancialData (
            double key,
            double open,
            double high,
            double low,
            double close )
```

Constructs a data point with the specified *key* and OHLC values.

17.631.3 Member Function Documentation

17.631.3.1 fromSortKey()

```
static QCPFinancialData QCPFinancialData::fromSortKey (
            double sortKey )  [inline], [static]
```

Returns a data point with the specified *sortKey*. All other members are set to zero.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.631.3.2 mainKey()

```
double QCPFinancialData::mainKey ( ) const  [inline]
```

Returns the *key* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.631.3.3 mainValue()

```
double QCPFinancialData::mainValue ( ) const  [inline]
```

Returns the *open* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.631.3.4 sortKey()

```
double QCPFinancialData::sortKey ( ) const  [inline]
```

Returns the *key* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.631.3.5 sortKeyIsMainKey()

```
static static bool QCPFinancialData::sortKeyIsMainKey ( )  [inline], [static]
```

Since the member *key* is both the data point key coordinate and the data ordering parameter, this method returns true.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.631.3.6 valueRange()

```
QCPRange QCPFinancialData::valueRange ( ) const  [inline]
```

Returns a QCPRange spanning from the *low* to the *high* value of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.632.1 Detailed Description

A plottable representing a graph in a plot.
Usually you create new graphs by calling QCustomPlot::addGraph. The resulting instance can be accessed via QCustomPlot::graph.
To plot data, assign it with the setData or addData functions. Alternatively, you can also access and modify the data via the data method, which returns a pointer to the internal QCPGraphDataContainer.
Graphs are used to display single-valued data. Single-valued means that there should only be one data point per unique key coordinate. In other words, the graph can't have *loops*. If you do want to plot non-single-valued curves, rather use the QCPCurve plottable.
Gaps in the graph line can be created by adding data points with NaN as value (`qQNaN()` or `std::numeric_limits<double>::quiet_NaN()`) in between the two data points that shall be separated.

17.632.2 Changing the appearance

The appearance of the graph is mainly determined by the line style, scatter style, brush and pen of the graph (setLineStyle, setScatterStyle, setBrush, setPen).

17.632.2.1 Filling under or between graphs

QCPGraph knows two types of fills: Normal graph fills towards the zero-value-line parallel to the key axis of the graph, and fills between two graphs, called channel fills. To enable a fill, just set a brush with setBrush which is neither Qt::NoBrush nor fully transparent.
By default, a normal fill towards the zero-value-line will be drawn. To set up a channel fill between this graph and another one, call setChannelFillGraph with the other graph as parameter.

QCustomPlot::addGraph, QCustomPlot::graph

17.632.3 Member Enumeration Documentation

17.632.3.1 LineStyle

`enum QCPGraph::LineStyle`
Defines how the graph's line is represented visually in the plot. The line is drawn with the current pen of the graph (setPen).

See also

setLineStyle

Enumerator

lsNone	with symbols according to the scatter style, see setScatterStyle) data points are not connected with any lines (e.g. data only represented
lsLine	data points are connected by a straight line
lsStepLeft	line is drawn as steps where the step height is the value of the left data point
lsStepRight	line is drawn as steps where the step height is the value of the right data point
lsStepCenter	line is drawn as steps where the step is in between two data points
lsImpulse	each data point is represented by a line parallel to the value axis, which reaches from the data point to the zero-value-line

17.632.4 Constructor & Destructor Documentation

17.632.4.1 QCPGraph()

`QCPGraph::QCPGraph (`

```
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )  [explicit]
```

Constructs a graph which uses *keyAxis* as its key axis ("x") and *valueAxis* as its value axis ("y"). *keyAxis* and *valueAxis* must reside in the same QCustomPlot instance and not have the same orientation. If either of these restrictions is violated, a corresponding message is printed to the debug output (qDebug), the construction is not aborted, though.
The created QCPGraph is automatically registered with the QCustomPlot instance inferred from *keyAxis*. This QCustomPlot instance takes ownership of the QCPGraph, so do not delete it manually but use QCustomPlot::removePlottable() instead.
To directly create a graph inside a plot, you can also use the simpler QCustomPlot::addGraph function.

17.632.5 Member Function Documentation

17.632.5.1 addData() [1/2]

```
void QCPGraph::addData (
            const QVector< double > & keys,
            const QVector< double > & values,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds the provided points in *keys* and *values* to the current data. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.
If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.
Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.632.5.2 addData() [2/2]

```
void QCPGraph::addData (
            double key,
            double value )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Adds the provided data point as *key* and *value* to the current data.
Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.632.5.3 data()

```
QSharedPointer< QCPGraphDataContainer > QCPGraph::data ( ) const  [inline]
```

Returns a shared pointer to the internal data storage of type QCPGraphDataContainer. You may use it to directly manipulate the data, which may be more convenient and faster than using the regular setData or addData methods.

17.632.5.4 draw()

```
void QCPGraph::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.632.5.5 drawLegendIcon()

```
void QCPGraph::drawLegendIcon (
            QCPPainter * painter,
            const QRectF & rect ) const  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.632.5.6 getKeyRange()

```
QCPRange QCPGraph::getKeyRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth ) const  [virtual]
```

Returns the coordinate range that all data in this plottable span in the key axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSignDomain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getValueRange

Implements QCPAbstractPlottable.

17.632.5.7 getValueRange()

```
QCPRange QCPGraph::getValueRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth,
            const QCPRange & inKeyRange = QCPRange() ) const  [virtual]
```

Returns the coordinate range that the data points in the specified key range (*inKeyRange*) span in the value axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSign↩ Domain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
If *inKeyRange* has both lower and upper bound set to zero (is equal to `QCPRange()`), all data points are considered, without any restriction on the keys.
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getKeyRange

Implements QCPAbstractPlottable.

17.632.5.8 getVisibleDataBounds()

```
void QCPGraph::getVisibleDataBounds (
            QCPGraphDataContainer::const_iterator & begin,
            QCPGraphDataContainer::const_iterator & end,
            const QCPDataRange & rangeRestriction ) const  [protected]
```

This method outputs the currently visible data range via *begin* and *end*. The returned range will also never exceed *rangeRestriction*.
This method takes into account that the drawing of data lines at the axis rect border always requires the points just outside the visible axis range. So *begin* and *end* may actually indicate a range that contains one additional data point to the left and right of the visible axis range.

17.632.5.9 selectTest()

```
double QCPGraph::selectTest (
            const QPointF & pos,
```

```
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Implements a selectTest specific to this plottable's point geometry.
If *details* is not 0, it will be set to a QCPDataSelection, describing the closest data point to *pos*.
\seebaseclassmethod QCPAbstractPlottable::selectTest
Reimplemented from QCPAbstractPlottable1D< QCPGraphData >.

17.632.5.10 setAdaptiveSampling()

```
void QCPGraph::setAdaptiveSampling (
            bool enabled )
```

Sets whether adaptive sampling shall be used when plotting this graph. QCustomPlot's adaptive sampling technique can drastically improve the replot performance for graphs with a larger number of points (e.g. above 10,000), without notably changing the appearance of the graph.
By default, adaptive sampling is enabled. Even if enabled, QCustomPlot decides whether adaptive sampling shall actually be used on a per-graph basis. So leaving adaptive sampling enabled has no disadvantage in almost all cases.
As can be seen, line plots experience no visual degradation from adaptive sampling. Outliers are reproduced reliably, as well as the overall shape of the data set. The replot time reduces dramatically though. This allows QCustomPlot to display large amounts of data in realtime.
Care must be taken when using high-density scatter plots in combination with adaptive sampling. The adaptive sampling algorithm treats scatter plots more carefully than line plots which still gives a significant reduction of replot times, but not quite as much as for line plots. This is because scatter plots inherently need more data points to be preserved in order to still resemble the original, non-adaptive-sampling plot. As shown above, the results still aren't quite identical, as banding occurs for the outer data points. This is in fact intentional, such that the boundaries of the data cloud stay visible to the viewer. How strong the banding appears, depends on the point density, i.e. the number of points in the plot.
For some situations with scatter plots it might thus be desirable to manually turn adaptive sampling off. For example, when saving the plot to disk. This can be achieved by setting *enabled* to false before issuing a command like QCustomPlot::savePng, and setting *enabled* back to true afterwards.

17.632.5.11 setChannelFillGraph()

```
void QCPGraph::setChannelFillGraph (
            QCPGraph * targetGraph )
```

Sets the target graph for filling the area between this graph and *targetGraph* with the current brush (setBrush).
When *targetGraph* is set to 0, a normal graph fill to the zero-value-line will be shown. To disable any filling, set the brush to Qt::NoBrush.

See also

setBrush

17.632.5.12 setData() [1/2]

```
void QCPGraph::setData (
            const QVector< double > & keys,
            const QVector< double > & values,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data with the provided points in *keys* and *values*. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.
If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.

See also

addData

17.632.5.13 setData() [2/2]

```
void QCPGraph::setData (
            QSharedPointer< QCPGraphDataContainer > data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data container with the provided *data* container.
Since a QSharedPointer is used, multiple QCPGraphs may share the same data container safely. Modifying the data in the container will then affect all graphs that share the container. Sharing can be achieved by simply exchanging the data containers wrapped in shared pointers:
If you do not wish to share containers, but create a copy from an existing container, rather use the QCPDataContainer<DataType>::set method on the graph's data container directly:

See also

addData

17.632.5.14 setLineStyle()

```
void QCPGraph::setLineStyle (
            LineStyle ls )
```

Sets how the single data points are connected in the plot. For scatter-only plots, set *ls* to lsNone and setScatterStyle to the desired scatter style.

See also

setScatterStyle

17.632.5.15 setScatterSkip()

```
void QCPGraph::setScatterSkip (
            int skip )
```

If scatters are displayed (scatter style not QCPScatterStyle::ssNone), *skip* number of scatter points are skipped/not drawn after every drawn scatter point.
This can be used to make the data appear sparser while for example still having a smooth line, and to improve performance for very high density plots.
If *skip* is set to 0 (default), all scatter points are drawn.

See also

setScatterStyle

17.632.5.16 setScatterStyle()

```
void QCPGraph::setScatterStyle (
            const QCPScatterStyle & style )
```

Sets the visual appearance of single data points in the plot. If set to QCPScatterStyle::ssNone, no scatter points are drawn (e.g. for line-only-plots with appropriate line style).

See also

QCPScatterStyle, setLineStyle

- applications/gui/genesys/qcustomplot.cpp

17.633 QCPGraphData Class Reference

Holds the data of one single data point for QCPGraph.

Public Member Functions

- QCPGraphData ()
- QCPGraphData (double key, double value)
- double sortKey () const
- double mainKey () const
- double mainValue () const
- QCPRange valueRange () const

Static Public Member Functions

- static QCPGraphData fromSortKey (double sortKey)
- static bool sortKeyIsMainKey ()

Public Attributes

- double **key**
- double **value**

17.633.1 Detailed Description

Holds the data of one single data point for QCPGraph.
The stored data is:

- *key:* coordinate on the key axis of this data point (this is the *mainKey* and the *sortKey*)
- *value:* coordinate on the value axis of this data point (this is the *mainValue*)

The container for storing multiple data points is QCPGraphDataContainer. It is a typedef for QCPDataContainer with QCPGraphData as the DataType template parameter. See the documentation there for an explanation regarding the data type's generic methods.

See also

QCPGraphDataContainer

17.633.2 Constructor & Destructor Documentation

17.633.2.1 QCPGraphData() [1/2]

```
QCPGraphData::QCPGraphData ( )
```

Constructs a data point with key and value set to zero.

17.633.2.2 QCPGraphData() [2/2]

```
QCPGraphData::QCPGraphData (
            double key,
            double value )
```

Constructs a data point with the specified *key* and *value*.

17.633.3 Member Function Documentation

17.633.3.1 fromSortKey()

```
static QCPGraphData QCPGraphData::fromSortKey (
            double sortKey )  [inline], [static]
```

Returns a data point with the specified *sortKey*. All other members are set to zero.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.633.3.2 mainKey()

```
double QCPGraphData::mainKey ( ) const  [inline]
```

Returns the *key* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.633.3.3 mainValue()

```
double QCPGraphData::mainValue ( ) const  [inline]
```

Returns the *value* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.633.3.4 sortKey()

```
double QCPGraphData::sortKey ( ) const  [inline]
```

Returns the *key* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.633.3.5 sortKeyIsMainKey()

```
static static bool QCPGraphData::sortKeyIsMainKey ( )  [inline], [static]
```

Since the member *key* is both the data point key coordinate and the data ordering parameter, this method returns true.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.633.3.6 valueRange()

```
QCPRange QCPGraphData::valueRange ( ) const  [inline]
```

Returns a QCPRange with both lower and upper boundary set to *value* of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.634.1 Detailed Description

Responsible for drawing the grid of a QCPAxis.
This class is tightly bound to QCPAxis. Every axis owns a grid instance and uses it to draw the grid lines, sub grid lines and zero-line. You can interact with the grid of an axis via QCPAxis::grid. Normally, you don't need to create an instance of QCPGrid yourself.
The axis and grid drawing was split into two classes to allow them to be placed on different layers (both QCPAxis and QCPGrid inherit from QCPLayerable). Thus it is possible to have the grid in the background and the axes in the foreground, and any plottables/items in between. This described situation is the default setup, see the QCPLayer documentation.

17.634.2 Constructor & Destructor Documentation

17.634.2.1 QCPGrid()

```
QCPGrid::QCPGrid (
            QCPAxis * parentAxis )  [explicit]
```

Creates a QCPGrid instance and sets default values.
You shouldn't instantiate grids on their own, since every QCPAxis brings its own QCPGrid.

17.634.3 Member Function Documentation

17.634.3.1 applyDefaultAntialiasingHint()

```
void QCPGrid::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Implements QCPLayerable.

17.634.3.2 draw()

```
void QCPGrid::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPLayerable.

17.634.3.3 setAntialiasedSubGrid()

```
void QCPGrid::setAntialiasedSubGrid (
            bool enabled )
```

Sets whether sub grid lines are drawn antialiased.

17.634.3.4 setAntialiasedZeroLine()

```
void QCPGrid::setAntialiasedZeroLine (
            bool enabled )
```

Sets whether zero lines are drawn antialiased.

17.634.3.5 setPen()

```
void QCPGrid::setPen (
            const QPen & pen )
```

Sets the pen with which (major) grid lines are drawn.

17.634.3.6 setSubGridPen()

```
void QCPGrid::setSubGridPen (
            const QPen & pen )
```

Sets the pen with which sub grid lines are drawn.

17.634.3.7 setSubGridVisible()

```
void QCPGrid::setSubGridVisible (
            bool visible )
```

Sets whether grid lines at sub tick marks are drawn.

See also

setSubGridPen

17.634.3.8 setZeroLinePen()

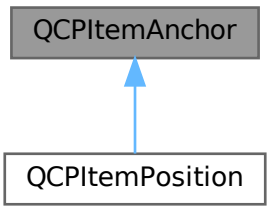
```
void QCPGrid::setZeroLinePen (
            const QPen & pen )
```

Sets the pen with which zero lines are drawn.
Zero lines are lines at value coordinate 0 which may be drawn with a different pen than other grid lines. To disable zero lines and just draw normal grid lines at zero, set *pen* to Qt::NoPen.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.635 QCPItemAnchor Class Reference

An anchor of an item to which positions can be attached to.
Inheritance diagram for QCPItemAnchor:



Collaboration diagram for QCPItemAnchor:

- QSet< QCPItemPosition * > **mChildrenX**
- QSet< QCPItemPosition * > **mChildrenY**

Friends

- class **QCPItemPosition**

17.635.1 Detailed Description

An anchor of an item to which positions can be attached to.
An item (QCPAbstractItem) may have one or more anchors. Unlike QCPItemPosition, an anchor doesn't control anything on its item, but provides a way to tie other items via their positions to the anchor.

For example, a QCPItemRect is defined by its positions *topLeft* and *bottomRight*. Additionally it has various anchors like *top*, *topRight* or *bottomLeft* etc. So you can attach the *start* (which is a QCPItemPosition) of a QCPItemLine to one of the anchors by calling QCPItemPosition::setParentAnchor on *start*, passing the wanted anchor of the QCPItemRect. This way the start of the line will now always follow the respective anchor location on the rect item.
Note that QCPItemPosition derives from QCPItemAnchor, so every position can also serve as an anchor to other positions.
To learn how to provide anchors in your own item subclasses, see the subclassing section of the QCPAbstractItem documentation.

17.635.2 Constructor & Destructor Documentation

17.635.2.1 QCPItemAnchor()

```
QCPItemAnchor::QCPItemAnchor (
            QCustomPlot * parentPlot,
            QCPAbstractItem * parentItem,
            const QString & name,
            int anchorId = -1 )
```

Creates a new QCPItemAnchor. You shouldn't create QCPItemAnchor instances directly, even if you want to make a new item subclass. Use QCPAbstractItem::createAnchor instead, as explained in the subclassing section of the QCPAbstractItem documentation.

17.635.3 Member Function Documentation

17.635.3.1 pixelPosition()

```
QPointF QCPItemAnchor::pixelPosition ( ) const  [virtual]
```

Returns the final absolute pixel position of the QCPItemAnchor on the QCustomPlot surface.
The pixel information is internally retrieved via QCPAbstractItem::anchorPixelPosition of the parent item, QCPItemAnchor is just an intermediary.
Reimplemented in QCPItemPosition.

17.635.3.2 toQCPItemPosition()

```
QCPItemPosition * QCPItemAnchor::toQCPItemPosition ( )  [inline], [protected], [virtual]
```

Returns `nullptr` if this instance is merely a QCPItemAnchor, and a valid pointer of type QCPItemPosition* if it actually is a QCPItemPosition (which is a subclass of QCPItemAnchor).
This safe downcast functionality could also be achieved with a dynamic_cast. However, QCustomPlot avoids dynamic_cast to work with projects that don't have RTTI support enabled (e.g. -fno-rtti flag with gcc compiler).
Reimplemented in QCPItemPosition.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.636 QCPItemBracket Class Reference

17.636.1 Detailed Description

A bracket for referencing/highlighting certain parts in the plot.
It has two positions, *left* and *right*, which define the span of the bracket. If *left* is actually farther to the left than *right*, the bracket is opened to the bottom, as shown in the example image.
The bracket supports multiple styles via setStyle. The length, i.e. how far the bracket stretches away from the embraced span, can be controlled with setLength.

Demonstrating the effect of different values for setLength, for styles bsCalligraphic and bsSquare. Anchors and positions are displayed for reference.

It provides an anchor *center*, to allow connection of other items, e.g. an arrow (QCPItemLine or QCPItemCurve) or a text label (QCPItemText), to the bracket.

17.636.2 Member Enumeration Documentation

17.636.2.1 BracketStyle

```
enum QCPItemBracket::BracketStyle
```

Defines the various visual shapes of the bracket item. The appearance can be further modified by setLength and setPen.

See also

setStyle

Enumerator

bsSquare	A brace with angled edges.
bsRound	A brace with round edges.
bsCurly	A curly brace.
bsCalligraphic	A curly brace with varying stroke width giving a calligraphic impression.

17.636.3 Constructor & Destructor Documentation

17.636.3.1 QCPItemBracket()

```
QCPItemBracket::QCPItemBracket (
            QCustomPlot * parentPlot )  [explicit]
```

Creates a bracket item and sets default values.
The created item is automatically registered with *parentPlot*. This QCustomPlot instance takes ownership of the item, so do not delete it manually but use QCustomPlot::removeItem() instead.

17.636.4 Member Function Documentation

17.636.4.1 anchorPixelPosition()

```
QPointF QCPItemBracket::anchorPixelPosition (
```

```
            int anchorId ) const  [protected], [virtual]
```
Reimplemented from QCPAbstractItem.

17.636.4.2 draw()

```
void QCPItemBracket::draw (
            QCPPainter * painter )  [protected], [virtual]
```
Implements QCPAbstractItem.

17.636.4.3 selectTest()

```
double QCPItemBracket::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```
This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

See also

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Implements QCPAbstractItem.

17.636.4.4 setLength()

```
void QCPItemBracket::setLength (
            double length )
```
Sets the *length* in pixels how far the bracket extends in the direction towards the embraced span of the bracket (i.e. perpendicular to the *left-right*-direction)

Demonstrating the effect of different values for setLength, for styles bsCalligraphic and bsSquare. Anchors and positions are displayed for reference.

17.636.4.5 setPen()

```
void QCPItemBracket::setPen (
            const QPen & pen )
```
Sets the pen that will be used to draw the bracket.
Note that when the style is bsCalligraphic, only the color will be taken from the pen, the stroke and width are ignored. To change the apparent stroke width of a calligraphic bracket, use setLength, which has a similar effect.

See also

setSelectedPen

17.636.4.6 setSelectedPen()

```
void QCPItemBracket::setSelectedPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the bracket when selected

See also

setPen, setSelected

17.636.4.7 setStyle()

```
void QCPItemBracket::setStyle (
            QCPItemBracket::BracketStyle style )
```

Sets the style of the bracket, i.e. the shape/visual appearance.

17.637.1 Detailed Description

A curved line from one point to another.
It has four positions, *start* and *end*, which define the end points of the line, and two control points which define the direction the line exits from the start and the direction from which it approaches the end: *startDir* and *endDir*.
With setHead and setTail you may set different line ending styles, e.g. to create an arrow.
Often it is desirable for the control points to stay at fixed relative positions to the start/end point. This can be achieved by setting the parent anchor e.g. of *startDir* simply to *start*, and then specify the desired pixel offset with QCPItemPosition::setCoords on *startDir*.

17.637.2 Constructor & Destructor Documentation

17.637.2.1 QCPItemCurve()

```
QCPItemCurve::QCPItemCurve (
            QCustomPlot * parentPlot )  [explicit]
```

Creates a curve item and sets default values.
The created item is automatically registered with *parentPlot*. This QCustomPlot instance takes ownership of the item, so do not delete it manually but use QCustomPlot::removeItem() instead.

17.637.3 Member Function Documentation

17.637.3.1 draw()

```
void QCPItemCurve::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractItem.

17.637.3.2 selectTest()

```
double QCPItemCurve::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

See also

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Implements QCPAbstractItem.

17.637.3.3 setHead()

```
void QCPItemCurve::setHead (
            const QCPLineEnding & head )
```

Sets the line ending style of the head. The head corresponds to the *end* position.
Note that due to the overloaded QCPLineEnding constructor, you may directly specify a QCPLineEnding::EndingStyle here, e.g.
`setHead(QCPLineEnding::esSpikeArrow)`

See also

setTail

17.637.3.4 setPen()

```
void QCPItemCurve::setPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the line

See also

setSelectedPen

17.637.3.5 setSelectedPen()

```
void QCPItemCurve::setSelectedPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the line when selected

See also

setPen, setSelected

17.637.3.6 setTail()

```
void QCPItemCurve::setTail (
            const QCPLineEnding & tail )
```

Sets the line ending style of the tail. The tail corresponds to the *start* position.
Note that due to the overloaded QCPLineEnding constructor, you may directly specify a QCPLineEnding::EndingStyle here, e.g.

```
setTail(QCPLineEnding::esSpikeArrow)
```

17.638.1 Detailed Description

An ellipse.
It has two positions, *topLeft* and *bottomRight*, which define the rect the ellipse will be drawn in.

17.638.2 Constructor & Destructor Documentation

17.638.2.1 QCPItemEllipse()

```
QCPItemEllipse::QCPItemEllipse (
            QCustomPlot * parentPlot )  [explicit]
```

Creates an ellipse item and sets default values.
The created item is automatically registered with *parentPlot*. This QCustomPlot instance takes ownership of the item, so do not delete it manually but use QCustomPlot::removeItem() instead.

17.638.3 Member Function Documentation

17.638.3.1 anchorPixelPosition()

```
QPointF QCPItemEllipse::anchorPixelPosition (
            int anchorId ) const  [protected], [virtual]
```

Reimplemented from QCPAbstractItem.

17.638.3.2 draw()

```
void QCPItemEllipse::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractItem.

17.638.3.3 selectTest()

```
double QCPItemEllipse::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. 17.639.1 Detailed Description

A line from one point to another.
It has two positions, *start* and *end*, which define the end points of the line.
With setHead and setTail you may set different line ending styles, e.g. to create an arrow.

17.639.2 Constructor & Destructor Documentation

17.639.2.1 QCPItemLine()

```
QCPItemLine::QCPItemLine (
            QCustomPlot * parentPlot )  [explicit]
```

Creates a line item and sets default values.
The created item is automatically registered with *parentPlot*. This QCustomPlot instance takes ownership of the item, so do not delete it manually but use QCustomPlot::removeItem() instead.

17.639.3 Member Function Documentation

17.639.3.1 draw()

```
void QCPItemLine::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractItem.

17.639.3.2 selectTest()

```
double QCPItemLine::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99*selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

Implements QCPAbstractItem.

17.639.3.3 setHead()

```
void QCPItemLine::setHead (
            const QCPLineEnding & head )
```

Sets the line ending style of the head. The head corresponds to the *end* position.
Note that due to the overloaded QCPLineEnding constructor, you may directly specify a QCPLineEnding::EndingStyle here, e.g.
`setHead(QCPLineEnding::esSpikeArrow)`

See also

setTail

17.639.3.4 setPen()

```
void QCPItemLine::setPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the line

See also

setSelectedPen

17.639.3.5 setSelectedPen()

```
void QCPItemLine::setSelectedPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the line when selected

See also

setPen, setSelected

17.639.3.6 setTail()

```
void QCPItemLine::setTail (
            const QCPLineEnding & tail )
```

Sets the line ending style of the tail. The tail corresponds to the *start* position.
Note that due to the overloaded QCPLineEnding constructor, you may directly specify a QCPLineEnding::EndingStyle here, e.g.
`setTail(QCPLineEnding::esSpikeArrow)`

17.640.1 Detailed Description

An arbitrary pixmap.
It has two positions, *topLeft* and *bottomRight*, which define the rectangle the pixmap will be drawn in. Depending on the scale setting (setScaled), the pixmap will be either scaled to fit the rectangle or be drawn aligned to the topLeft position.
If scaling is enabled and *topLeft* is further to the bottom/right than *bottomRight* (as shown on the right side of the example image), the pixmap will be flipped in the respective orientations.

17.640.2 Constructor & Destructor Documentation

17.640.2.1 QCPItemPixmap()

```
QCPItemPixmap::QCPItemPixmap (
            QCustomPlot * parentPlot )  [explicit]
```

Creates a rectangle item and sets default values.
The created item is automatically registered with *parentPlot*. This QCustomPlot instance takes ownership of the item, so do not delete it manually but use QCustomPlot::removeItem() instead.

17.640.3 Member Function Documentation

17.640.3.1 anchorPixelPosition()

```
QPointF QCPItemPixmap::anchorPixelPosition (
            int anchorId ) const  [protected], [virtual]
```

Reimplemented from QCPAbstractItem.

17.640.3.2 draw()

```
void QCPItemPixmap::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractItem.

17.640.3.3 selectTest()

```
double QCPItemPixmap::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.

pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Implements QCPAbstractItem.

17.640.3.4 setPen()

```
void QCPItemPixmap::setPen (
            const QPen & pen )
```

Sets the pen that will be used to draw a border around the pixmap.

See also

setSelectedPen, setBrush

17.640.3.5 setPixmap()

```
void QCPItemPixmap::setPixmap (
            const QPixmap & pixmap )
```

Sets the pixmap that will be displayed.

17.640.3.6 setScaled()

```
void QCPItemPixmap::setScaled (
            bool scaled,
            Qt::AspectRatioMode aspectRatioMode = Qt::KeepAspectRatio,
            Qt::TransformationMode transformationMode = Qt::SmoothTransformation )
```

Sets whether the pixmap will be scaled to fit the rectangle defined by the *topLeft* and *bottomRight* positions.

17.640.3.7 setSelectedPen()

```
void QCPItemPixmap::setSelectedPen (
            const QPen & pen )
```

Sets the pen that will be used to draw a border around the pixmap when selected

17.641.1 Detailed Description

Manages the position of an item.
Every item has at least one public QCPItemPosition member pointer which provides ways to position the item on the QCustomPlot surface. Some items have multiple positions, for example QCPItemRect has two: *topLeft* and *bottomRight*.
QCPItemPosition has a type (PositionType) that can be set with setType. This type defines how coordinates passed to setCoords are to be interpreted, e.g. as absolute pixel coordinates, as plot coordinates of certain axes (QCPItemPosition::setAxes), as fractions of the axis rect (QCPItemPosition::setAxisRect), etc. For more advanced plots it is also possible to assign different types per X/Y coordinate of the position (see setTypeX, setTypeY). This way an item could be positioned for example at a fixed pixel distance from the top in the Y direction, while following a plot coordinate in the X direction.
A QCPItemPosition may have a parent QCPItemAnchor, see setParentAnchor. This way you can tie multiple items together. If the QCPItemPosition has a parent, its coordinates (setCoords) are considered to be absolute pixels in the reference frame of the parent anchor, where (0, 0) means directly ontop of the parent anchor. For example, You could attach the *start* position of a QCPItemLine to the *bottom* anchor of a QCPItemText to make the starting point of the line always be centered under the text label, no matter where the text is moved to. For more advanced plots, it is possible to assign different parent anchors per X/Y coordinate of the position, see setParentAnchorX, setParentAnchorY. This way an item could follow another item in the X direction but stay at a fixed position in the Y direction. Or even follow item A in X, and item B in Y.
Note that every QCPItemPosition inherits from QCPItemAnchor and thus can itself be used as parent anchor for other positions.
To set the apparent pixel position on the QCustomPlot surface directly, use setPixelPosition. This works no matter what type this QCPItemPosition is or what parent-child situation it is in, as setPixelPosition transforms the coordinates appropriately, to make the position appear at the specified pixel values.

17.641.2 Member Enumeration Documentation

17.641.2.1 PositionType

`enum QCPItemPosition::PositionType`
Defines the ways an item position can be specified. Thus it defines what the numbers passed to setCoords actually mean.

See also

setType

Enumerator

ptAbsolute	Static positioning in pixels, starting from the top left corner of the viewport/widget.
ptViewportRatio	Static positioning given by a fraction of the viewport size. For example, if you call setCoords(0, 0), the position will be at the top left corner of the viewport/widget. setCoords(1, 1) will be at the bottom right corner, setCoords(0.5, 0) will be horizontally centered and vertically at the top of the viewport/widget, etc.
ptAxisRectRatio	Static positioning given by a fraction of the axis rect size (see setAxisRect). For example, if you call setCoords(0, 0), the position will be at the top left corner of the axis rect. setCoords(1, 1) will be at the bottom right corner, setCoords(0.5, 0) will be horizontally centered and vertically at the top of the axis rect, etc. You can also go beyond the axis rect by providing negative coordinates or coordinates larger than 1.
ptPlotCoords	Dynamic positioning at a plot coordinate defined by two axes (see setAxes).

17.641.3 Constructor & Destructor Documentation

17.641.3.1 QCPItemPosition()

```
QCPItemPosition::QCPItemPosition (
            QCustomPlot * parentPlot,
            QCPAbstractItem * parentItem,
            const QString & name )
```

Creates a new QCPItemPosition. You shouldn't create QCPItemPosition instances directly, even if you want to make a new item subclass. Use QCPAbstractItem::createPosition instead, as explained in the subclassing section of the QCPAbstractItem documentation.

17.641.4 Member Function Documentation

17.641.4.1 parentAnchor()

```
QCPItemAnchor * QCPItemPosition::parentAnchor ( ) const  [inline]
```

Returns the current parent anchor.
If different parent anchors were set for X and Y (setParentAnchorX, setParentAnchorY), this method returns the parent anchor of the Y coordinate. In that case rather use *parentAnchorX()* and *parentAnchorY()*.

See also

setParentAnchor

17.641.4.2 pixelPosition()

```
QPointF QCPItemPosition::pixelPosition ( ) const  [virtual]
```

Returns the final absolute pixel position of the QCPItemPosition on the QCustomPlot surface. It includes all effects of type (setType) and possible parent anchors (setParentAnchor).

See also

setPixelPosition

Reimplemented from QCPItemAnchor.

17.641.4.3 setAxes()

```
void QCPItemPosition::setAxes (
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )
```

When setType is ptPlotCoords, this function may be used to specify the axes the coordinates set with setCoords relate to. By default they are set to the initial xAxis and yAxis of the QCustomPlot.

17.641.4.4 setAxisRect()

```
void QCPItemPosition::setAxisRect (
            QCPAxisRect * axisRect )
```

When setType is ptAxisRectRatio, this function may be used to specify the axis rect the coordinates set with setCoords relate to. By default this is set to the main axis rect of the QCustomPlot.

17.641.4.5 setCoords() [1/2]

```
void QCPItemPosition::setCoords (
            const QPointF & pos )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the coordinates as a QPointF *pos* where pos.x has the meaning of *key* and pos.y the meaning of *value* of the setCoords(double key, double value) method.

17.641.4.6 setCoords() [2/2]

```
void QCPItemPosition::setCoords (
            double key,
            double value )
```

Sets the coordinates of this QCPItemPosition. What the coordinates mean, is defined by the type (setType, setTypeX, setTypeY).
For example, if the type is ptAbsolute, *key* and *value* mean the x and y pixel position on the QCustomPlot surface. In that case the origin (0, 0) is in the top left corner of the QCustomPlot viewport. If the type is ptPlotCoords, *key* and *value* mean a point in the plot coordinate system defined by the axes set by setAxes. By default those are the QCustomPlot's xAxis and yAxis. See the documentation of setType for other available coordinate types and their meaning.
If different types were configured for X and Y (setTypeX, setTypeY), *key* and *value* must also be provided in the different coordinate systems. Here, the X type refers to *key*, and the Y type refers to *value*.

See also

setPixelPosition

17.641.4.7 setParentAnchor()

```
bool QCPItemPosition::setParentAnchor (
            QCPItemAnchor * parentAnchor,
            bool keepPixelPosition = false )
```

Sets the parent of this QCPItemPosition to *parentAnchor*. This means the position will now follow any position changes of the anchor. The local coordinate system of positions with a parent anchor always is absolute pixels, with (0, 0) being exactly on top of the parent anchor. (Hence the type shouldn't be set to ptPlotCoords for positions with parent anchors.)
if *keepPixelPosition* is true, the current pixel position of the QCPItemPosition is preserved during reparenting. If it's set to false, the coordinates are set to (0, 0), i.e. the position will be exactly on top of the parent anchor.
To remove this QCPItemPosition from any parent anchor, set *parentAnchor* to `nullptr`.
If the QCPItemPosition previously had no parent and the type is ptPlotCoords, the type is set to ptAbsolute, to keep the position in a valid state.
This method sets the parent anchor for both X and Y directions. It is also possible to set different parents for X and Y, see setParentAnchorX, setParentAnchorY.

17.641.4.8 setParentAnchorX()

```
bool QCPItemPosition::setParentAnchorX (
            QCPItemAnchor * parentAnchor,
            bool keepPixelPosition = false )
```

This method sets the parent anchor of the X coordinate to *parentAnchor*.
For a detailed description of what a parent anchor is, see the documentation of setParentAnchor.

See also

setParentAnchor, setParentAnchorY

17.641.4.9 setParentAnchorY()

```
bool QCPItemPosition::setParentAnchorY (
            QCPItemAnchor * parentAnchor,
            bool keepPixelPosition = false )
```

This method sets the parent anchor of the Y coordinate to *parentAnchor*.
For a detailed description of what a parent anchor is, see the documentation of setParentAnchor.

See also

setParentAnchor, setParentAnchorX

17.641.4.10 setPixelPosition()

```
void QCPItemPosition::setPixelPosition (
            const QPointF & pixelPosition )
```

Sets the apparent pixel position. This works no matter what type (setType) this QCPItemPosition is or what parent-child situation it is in, as coordinates are transformed appropriately, to make the position finally appear at the specified pixel values.
Only if the type is ptAbsolute and no parent anchor is set, this function's effect is identical to that of setCoords.

See also

pixelPosition, setCoords

17.641.4.11 setType()

```
void QCPItemPosition::setType (
            QCPItemPosition::PositionType type )
```

Sets the type of the position. The type defines how the coordinates passed to setCoords should be handled and how the QCPItemPosition should behave in the plot.
The possible values for *type* can be separated in two main categories:

- The position is regarded as a point in plot coordinates. This corresponds to ptPlotCoords and requires two axes that define the plot coordinate system. They can be specified with setAxes. By default, the QCustomPlot's x- and yAxis are used.
- The position is fixed on the QCustomPlot surface, i.e. independent of axis ranges. This corresponds to all other types, i.e. ptAbsolute, ptViewportRatio and ptAxisRectRatio. They differ only in the way the absolute position is described, see the documentation of PositionType for details. For ptAxisRectRatio, note that you can specify the axis rect with setAxisRect. By default this is set to the main axis rect.

Note that the position type ptPlotCoords is only available (and sensible) when the position has no parent anchor (setParentAnchor).
If the type is changed, the apparent pixel position on the plot is preserved. This means the coordinates as retrieved with coords() and set with setCoords may change in the process.
This method sets the type for both X and Y directions. It is also possible to set different types for X and Y, see setTypeX, setTypeY.

17.641.4.12 setTypeX()

```
void QCPItemPosition::setTypeX (
            QCPItemPosition::PositionType type )
```

This method sets the position type of the X coordinate to *type*.
For a detailed description of what a position type is, see the documentation of setType.

See also

setType, setTypeY

17.641.4.13 setTypeY()

```
void QCPItemPosition::setTypeY (
            QCPItemPosition::PositionType type )
```

This method sets the position type of the Y coordinate to *type*.
For a detailed description of what a position type is, see the documentation of setType.

See also

setType, setTypeX

17.641.4.14 toQCPItemPosition()

`virtual QCPItemPosition * QCPItemPosition::toQCPItemPosition ( ) [inline], [protected], [virtual]`
Returns `nullptr` if this instance is merely a QCPItemAnchor, and a valid pointer of type QCPItemPosition* if it actually is a QCPItemPosition (which is a subclass of QCPItemAnchor).
This safe downcast functionality could also be achieved with a dynamic_cast. However, QCustomPlot avoids dynamic_cast to work with projects that don't have RTTI support enabled (e.g. -fno-rtti flag with gcc compiler).
Reimplemented from QCPItemAnchor.

17.641.4.15 type()

`QCPItemPosition::PositionType * QCPItemPosition::type ( ) const [inline]`
Returns the current position type.
If different types were set for X and Y (setTypeX, setTypeY), this method returns the type of the X coordinate. In that case rather use *typeX()* and *typeY()*.

17.642.1 Detailed Description

A rectangle.
It has two positions, *topLeft* and *bottomRight*, which define the rectangle.

17.642.2 Constructor & Destructor Documentation

17.642.2.1 QCPItemRect()

```
QCPItemRect::QCPItemRect (
            QCustomPlot * parentPlot )  [explicit]
```

Creates a rectangle item and sets default values.
The created item is automatically registered with *parentPlot*. This QCustomPlot instance takes ownership of the item, so do not delete it manually but use QCustomPlot::removeItem() instead.

17.642.3 Member Function Documentation

17.642.3.1 anchorPixelPosition()

```
QPointF QCPItemRect::anchorPixelPosition (
            int anchorId ) const  [protected], [virtual]
```

Reimplemented from QCPAbstractItem.

17.642.3.2 draw()

```
void QCPItemRect::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractItem.

17.642.3.3 selectTest()

```
double QCPItemRect::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

Implements QCPAbstractItem.

17.642.3.4 setBrush()

```
void QCPItemRect::setBrush (
            const QBrush & brush )
```

Sets the brush that will be used to fill the rectangle. To disable filling, set *brush* to Qt::NoBrush.

See also

setSelectedBrush, setPen

17.642.3.5 setPen()

```
void QCPItemRect::setPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the line of the rectangle

See also

setSelectedPen, setBrush

17.642.3.6 setSelectedBrush()

```
void QCPItemRect::setSelectedBrush (
            const QBrush & brush )
```

Sets the brush that will be used to fill the rectangle when selected. To disable filling, set *brush* to Qt::NoBrush.

See also

setBrush

17.642.3.7 setSelectedPen()

```
void QCPItemRect::setSelectedPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the line of the rectangle when selected

17.644.1 Detailed Description

A text label.
Its position is defined by the member *position* and the setting of setPositionAlignment. The latter controls which part of the text rect shall be aligned with *position*.
The text alignment itself (i.e. left, center, right) can be controlled with setTextAlignment.
The text may be rotated around the *position* point with setRotation.

17.644.2 Constructor & Destructor Documentation

17.644.2.1 QCPItemText()

```
QCPItemText::QCPItemText (
            QCustomPlot * parentPlot )  [explicit]
```

Creates a text item and sets default values.
The created item is automatically registered with *parentPlot*. This QCustomPlot instance takes ownership of the item, so do not delete it manually but use QCustomPlot::removeItem() instead.

17.644.3 Member Function Documentation

17.644.3.1 anchorPixelPosition()

```
QPointF QCPItemText::anchorPixelPosition (
            int anchorId ) const  [protected], [virtual]
```

Reimplemented from QCPAbstractItem.

17.644.3.2 draw()

```
void QCPItemText::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractItem.

17.644.3.3 selectTest()

```
double QCPItemText::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

17.644.3.5 setColor()

```
void QCPItemText::setColor (
            const QColor & color )
```

Sets the color of the text.

17.644.3.6 setFont()

```
void QCPItemText::setFont (
            const QFont & font )
```

Sets the font of the text.

See also

setSelectedFont, setColor

17.644.3.7 setPadding()

```
void QCPItemText::setPadding (
            const QMargins & padding )
```

Sets the distance between the border of the text rectangle and the text. The appearance (and visibility) of the text rectangle can be controlled with setPen and setBrush.

17.644.3.8 setPen()

```
void QCPItemText::setPen (
            const QPen & pen )
```

Sets the pen that will be used do draw a rectangular border around the text. To disable the border, set *pen* to Qt::NoPen.

See also

setSelectedPen, setBrush, setPadding

17.644.3.9 setPositionAlignment()

```
void QCPItemText::setPositionAlignment (
            Qt::Alignment alignment )
```

Sets which point of the text rect shall be aligned with *position*.
Examples:

- If *alignment* is `Qt::AlignHCenter | Qt::AlignTop`, the text will be positioned such that the top of the text rect will be horizontally centered on *position*.
- If *alignment* is `Qt::AlignLeft | Qt::AlignBottom`, *position* will indicate the bottom left corner of the text rect.

If you want to control the alignment of (multi-lined) text within the text rect, use setTextAlignment.

17.644.3.10 setRotation()

```
void QCPItemText::setRotation (
            double degrees )
```

Sets the angle in degrees by which the text (and the text rectangle, if visible) will be rotated around *position*.

17.644.3.11 setSelectedBrush()

```
void QCPItemText::setSelectedBrush (
            const QBrush & brush )
```

Sets the brush that will be used do fill the background of the text, when the item is selected. To disable the background, set *brush* to Qt::NoBrush.

See also

setBrush

17.644.3.12 setSelectedColor()

```
void QCPItemText::setSelectedColor (
            const QColor & color )
```

Sets the color of the text that will be used when the item is selected.

17.644.3.13 setSelectedFont()

```
void QCPItemText::setSelectedFont (
            const QFont & font )
```

Sets the font of the text that will be used when the item is selected.

See also

setFont

17.644.3.14 setSelectedPen()

```
void QCPItemText::setSelectedPen (
            const QPen & pen )
```

Sets the pen that will be used do draw a rectangular border around the text, when the item is selected. To disable the border, set *pen* to Qt::NoPen.

See also

setPen

17.644.3.15 setText()

```
void QCPItemText::setText (
            const QString & text )
```

Sets the text that will be displayed. Multi-line texts are supported by inserting a line break character, e.g. '
'.

See also

setFont, setColor, setTextAlignment

17.644.3.16 setTextAlignment()

```
void QCPItemText::setTextAlignment (
            Qt::Alignment alignment )
```

Controls how (multi-lined) text is aligned inside the text rect (typically Qt::AlignLeft, Qt::AlignCenter or Qt::Align↩ Right).

17.645.1 Detailed Description

Item that sticks to QCPGraph data points.
The tracer can be connected with a QCPGraph via setGraph. Then it will automatically adopt the coordinate axes of the graph and update its *position* to be on the graph's data. This means the key stays controllable via setGraphKey, but the value will follow the graph data. If a QCPGraph is connected, note that setting the coordinates of the tracer item directly via *position* will have no effect because they will be overriden in the next redraw (this is when the coordinate update happens).
If the specified key in setGraphKey is outside the key bounds of the graph, the tracer will stay at the corresponding end of the graph.
With setInterpolating you may specify whether the tracer may only stay exactly on data points or whether it interpolates data points linearly, if given a key that lies between two data points of the graph.
The tracer has different visual styles, see setStyle. It is also possible to make the tracer have no own visual appearance (set the style to tsNone), and just connect other item positions to the tracer *position* (used as an anchor) via QCPItemPosition::setParentAnchor.

Note

The tracer position is only automatically updated upon redraws. So when the data of the graph changes and immediately afterwards (without a redraw) the position coordinates of the tracer are retrieved, they will not reflect the updated data of the graph. In this case updatePosition must be called manually, prior to reading the tracer coordinates.

17.645.2 Member Enumeration Documentation

17.645.2.1 TracerStyle

```
enum QCPItemTracer::TracerStyle
```

The different visual appearances a tracer item can have. Some styles size may be controlled with setSize.

See also

setStyle

Enumerator

tsNone	The tracer is not visible.
tsPlus	A plus shaped crosshair with limited size.
tsCrosshair	A plus shaped crosshair which spans the complete axis rect.
tsCircle	A circle.
tsSquare	A square.

17.645.3 Constructor & Destructor Documentation

17.645.3.1 QCPItemTracer()

```
QCPItemTracer::QCPItemTracer (
            QCustomPlot * parentPlot )  [explicit]
```

Creates a tracer item and sets default values.
The created item is automatically registered with *parentPlot*. This QCustomPlot instance takes ownership of the item, so do not delete it manually but use QCustomPlot::removeItem() instead.

17.645.4 Member Function Documentation

17.645.4.1 draw()

```
void QCPItemTracer::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractItem.

17.645.4.2 selectTest()

```
double QCPItemTracer::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

See also

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Implements QCPAbstractItem.

17.645.4.3 setBrush()

```
void QCPItemTracer::setBrush (
            const QBrush & brush )
```

Sets the brush that will be used to draw any fills of the tracer

See also

setSelectedBrush, setPen

17.645.4.4 setGraph()

```
void QCPItemTracer::setGraph (
            QCPGraph * graph )
```

Sets the QCPGraph this tracer sticks to. The tracer *position* will be set to type QCPItemPosition::ptPlotCoords and the axes will be set to the axes of *graph*.
To free the tracer from any graph, set *graph* to `nullptr`. The tracer *position* can then be placed freely like any other item position. This is the state the tracer will assume when its graph gets deleted while still attached to it.

See also

setGraphKey

17.645.4.5 setGraphKey()

```
void QCPItemTracer::setGraphKey (
            double key )
```

Sets the key of the graph's data point the tracer will be positioned at. This is the only free coordinate of a tracer when attached to a graph.
Depending on setInterpolating, the tracer will be either positioned on the data point closest to *key*, or will stay exactly at *key* and interpolate the value linearly.

See also

setGraph, setInterpolating

17.645.4.6 setInterpolating()

```
void QCPItemTracer::setInterpolating (
            bool enabled )
```

Sets whether the value of the graph's data points shall be interpolated, when positioning the tracer.
If *enabled* is set to false and a key is given with setGraphKey, the tracer is placed on the data point of the graph which is closest to the key, but which is not necessarily exactly there. If *enabled* is true, the tracer will be positioned exactly at the specified key, and the appropriate value will be interpolated from the graph's data points linearly.

See also

setGraph, setGraphKey

17.645.4.7 setPen()

```
void QCPItemTracer::setPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the line of the tracer

See also

setSelectedPen, setBrush

17.645.4.8 setSelectedBrush()

```
void QCPItemTracer::setSelectedBrush (
            const QBrush & brush )
```

Sets the brush that will be used to draw any fills of the tracer, when selected.

See also

setBrush, setSelected

17.645.4.9 setSelectedPen()

```
void QCPItemTracer::setSelectedPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the line of the tracer when selected

See also

setPen, setSelected

17.645.4.10 setSize()

```
void QCPItemTracer::setSize (
            double size )
```

Sets the size of the tracer in pixels, if the style supports setting a size (e.g. tsSquare does, tsCrosshair does not).

17.645.4.11 setStyle()

```
void QCPItemTracer::setStyle (
            QCPItemTracer::TracerStyle style )
```

Sets the style/visual appearance of the tracer.
If you only want to use the tracer *position* as an anchor for other items, set *style* to tsNone.

17.645.4.12 updatePosition()

```
void QCPItemTracer::updatePosition ( )
```

If the tracer is connected with a graph (setGraph), this function updates the tracer's *position* to reside on the graph data, depending on the configured key (setGraphKey).
It is called automatically on every redraw and normally doesn't need to be called manually. One exception is when you want to read the tracer coordinates via *position* and are not sure that the graph's data (or the tracer key with setGraphKey) hasn't changed since the last redraw. In that situation, call this function before accessing *position*, to make sure you don't get out-of-date coordinates.
If there is no graph set on this tracer, this function does nothing.

17.647.1 Detailed Description

A layer that may contain objects, to control the rendering order.
The Layering system of QCustomPlot is the mechanism to control the rendering order of the elements inside the plot.
It is based on the two classes QCPLayer and QCPLayerable. QCustomPlot holds an ordered list of one or more instances of QCPLayer (see QCustomPlot::addLayer, QCustomPlot::layer, QCustomPlot::moveLayer, etc.). When replotting, QCustomPlot goes through the list of layers bottom to top and successively draws the layerables of the layers into the paint buffer(s).
A QCPLayer contains an ordered list of QCPLayerable instances. QCPLayerable is an abstract base class from which almost all visible objects derive, like axes, grids, graphs, items, etc.

17.647.2 Default layers

Initially, QCustomPlot has six layers: "background", "grid", "main", "axes", "legend" and "overlay" (in that order). On top is the "overlay" layer, which only contains the QCustomPlot's selection rect (QCustomPlot::selectionRect). The next two layers "axes" and "legend" contain the default axes and legend, so they will be drawn above plottables. In the middle, there is the "main" layer. It is initially empty and set as the current layer (see QCustomPlot::setCurrentLayer). This means, all new plottables, items etc. are created on this layer by default. Then comes the "grid" layer which contains the QCPGrid instances (which belong tightly to QCPAxis, see QCPAxis::grid). The Axis rect background shall be drawn behind everything else, thus the default QCPAxisRect instance is placed on the "background" layer. Of course, the layer affiliation of the individual objects can be changed as required (QCPLayerable::setLayer).

17.647.3 Controlling the rendering order via layers

Controlling the ordering of layerables in the plot is easy: Create a new layer in the position you want the layerable to be in, e.g. above "main", with QCustomPlot::addLayer. Then set the current layer with QCustomPlot::setCurrentLayer to that new layer and finally create the objects normally. They will be placed on the new layer automatically, due to the current layer setting. Alternatively you could have also ignored the current layer setting and just moved the objects with QCPLayerable::setLayer to the desired layer after creating them.
It is also possible to move whole layers. For example, If you want the grid to be shown in front of all plottables/items on the "main" layer, just move it above "main" with QCustomPlot::moveLayer.
The rendering order within one layer is simply by order of creation or insertion. The item created last (or added last to the layer), is drawn on top of all other objects on that layer.
When a layer is deleted, the objects on it are not deleted with it, but fall on the layer below the deleted layer, see QCustomPlot::removeLayer.

17.647.4 Replotting only a specific layer

If the layer mode (setMode) is set to lmBuffered, you can replot only this specific layer by calling replot. In certain situations this can provide better replot performance, compared with a full replot of all layers. Upon creation of a new layer, the layer mode is initialized to lmLogical. The only layer that is set to lmBuffered in a new QCustomPlot instance is the "overlay" layer, containing the selection rect.

17.647.5 Member Enumeration Documentation

17.647.5.1 LayerMode

`enum QCPLayer::LayerMode`

Defines the different rendering modes of a layer. Depending on the mode, certain layers can be replotted individually, without the need to replot (possibly complex) layerables on other layers.

See also

setMode

Enumerator

lmLogical	Layer is used only for rendering order, and shares paint buffer with all other adjacent logical layers.
lmBuffered	Layer has its own paint buffer and may be replotted individually (see replot).

17.647.6 Constructor & Destructor Documentation

17.647.6.1 QCPLayer()

```
QCPLayer::QCPLayer (
            QCustomPlot * parentPlot,
            const QString & layerName )
```

Creates a new QCPLayer instance.
Normally you shouldn't directly instantiate layers, use QCustomPlot::addLayer instead.

Warning

It is not checked that *layerName* is actually a unique layer name in *parentPlot*. This check is only performed by QCustomPlot::addLayer.

17.647.7 Member Function Documentation

17.647.7.1 children()

`QList< QCPLayerable * > QCPLayer::children ( ) const [inline]`

Returns a list of all layerables on this layer. The order corresponds to the rendering order: layerables with higher indices are drawn above layerables with lower indices.

17.647.7.2 index()

`int QCPLayer::index ( ) const [inline]`

Returns the index this layer has in the QCustomPlot. The index is the integer number by which this layer can be accessed via QCustomPlot::layer.
Layers with higher indices will be drawn above layers with lower indices.

17.647.7.3 replot()

`void QCPLayer::replot ( )`

If the layer mode (setMode) is set to lmBuffered, this method allows replotting only the layerables on this specific layer, without the need to replot all other layers (as a call to QCustomPlot::replot would do).
QCustomPlot also makes sure to replot all layers instead of only this one, if the layer ordering or any layerable-layer-association has changed since the last full replot and any other paint buffers were thus invalidated.
If the layer mode is lmLogical however, this method simply calls QCustomPlot::replot on the parent QCustomPlot instance.

See also

draw

17.647.7.4 setMode()

```
void QCPLayer::setMode (
            QCPLayer::LayerMode mode )
```

Sets the rendering mode of this layer.
If *mode* is set to lmBuffered for a layer, it will be given a dedicated paint buffer by the parent QCustomPlot instance. This means it may be replotted individually by calling QCPLayer::replot, without needing to replot all other layers.
Layers which are set to lmLogical (the default) are used only to define the rendering order and can't be replotted individually.
Note that each layer which is set to lmBuffered requires additional paint buffers for the layers below, above and for the layer itself. This increases the memory consumption and (slightly) decreases the repainting speed because multiple paint buffers need to be joined. So you should carefully choose which layers benefit from having their own paint buffer. A typical example would be a layer which contains certain layerables (e.g. items) that need to be changed and thus replotted regularly, while all other layerables on other layers stay static. By default, only the topmost layer called "overlay" is in mode lmBuffered, and contains the selection rect.

See also

replot

17.647.7.5 setVisible()

```
void QCPLayer::setVisible (
            bool visible )
```

Sets whether this layer is visible or not. If *visible* is set to false, all layerables on this layer will be invisible.
This function doesn't change the visibility property of the layerables (QCPLayerable::setVisible), but the QCPLayerable::realVisibility of each layerable takes the visibility of the parent layer into account.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.648.1 Detailed Description

Base class for all drawable objects.
This is the abstract base class most visible objects derive from, e.g. plottables, axes, grid etc.
Every layerable is on a layer (QCPLayer) which allows controlling the rendering order by stacking the layers accordingly.
For details about the layering mechanism, see the QCPLayer documentation.

17.648.2 Constructor & Destructor Documentation

17.648.2.1 QCPLayerable()

```
QCPLayerable::QCPLayerable (
            QCustomPlot * plot,
            QString targetLayer = QString(),
            QCPLayerable * parentLayerable = nullptr )
```

Creates a new QCPLayerable instance.
Since QCPLayerable is an abstract base class, it can't be instantiated directly. Use one of the derived classes.
If *plot* is provided, it automatically places itself on the layer named *targetLayer*. If *targetLayer* is an empty string, it places itself on the current layer of the plot (see QCustomPlot::setCurrentLayer).
It is possible to provide `nullptr` as *plot*. In that case, you should assign a parent plot at a later time with initializeParentPlot.
The layerable's parent layerable is set to *parentLayerable*, if provided. Direct layerable parents are mainly used to control visibility in a hierarchy of layerables. This means a layerable is only drawn, if all its ancestor layerables are also visible. Note that *parentLayerable* does not become the QObject-parent (for memory management) of this layerable, *plot* does. It is not uncommon to set the QObject-parent to something else in the constructors of QCPLayerable subclasses, to guarantee a working destruction hierarchy.

17.648.3 Member Function Documentation

17.648.3.1 layerChanged

```
void QCPLayerable::layerChanged (
            QCPLayer * newLayer )  [signal]
```

This signal is emitted when the layer of this layerable changes, i.e. this layerable is moved to a different layer.

See also

setLayer

17.648.3.2 mouseDoubleClickEvent()

```
void QCPLayerable::mouseDoubleClickEvent (
            QMouseEvent * event,
            const QVariant & details )  [protected], [virtual]
```

This event gets called when the user presses the mouse button a second time in a double-click, while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The mouseDoubleClickEvent is called instead of the second mousePressEvent. So in the case of a double-click, the event succession is *pressEvent – releaseEvent – doubleClickEvent – releaseEvent*.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *details* contains layerable-specific details about the hit, which were generated in the previous call to selectTest. For example, One-dimensional plottables like QCPGraph or QCPBars convey the clicked data point in the *details* parameter, as QCPDataSelection packed as QVariant. Multi-part objects convey the specific `SelectablePart` that was hit (e.g. QCPAxis::SelectablePart in the case of axes).
Similarly to mousePressEvent, once a layerable has accepted the mouseDoubleClickEvent, it is considered the mouse grabber and will receive all following calls to mouseMoveEvent and mouseReleaseEvent for this mouse interaction (a "mouse interaction" in this context ends with the release).
The default implementation does nothing except explicitly ignoring the event with `event->ignore()`.

See also

mousePressEvent, mouseMoveEvent, mouseReleaseEvent, wheelEvent

Reimplemented in QCPTextElement.

17.648.3.3 mouseMoveEvent()

```
void QCPLayerable::mouseMoveEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user moves the mouse while holding a mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented in QCPAxis, QCPAxisRect, QCPColorScaleAxisRectPrivate, QCPColorScale, QCPPolarAxisRadial, and QCPPolarAxisAngular.

17.648.3.4 mousePressEvent()

```
void QCPLayerable::mousePressEvent (
            QMouseEvent * event,
            const QVariant & details )  [protected], [virtual]
```

This event gets called when the user presses a mouse button while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.

The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *details* contains layerable-specific details about the hit, which were generated in the previous call to selectTest. For example, One-dimensional plottables like QCPGraph or QCPBars convey the clicked data point in the *details* parameter, as QCPDataSelection packed as QVariant. Multi-part objects convey the specific `SelectablePart` that was hit (e.g. QCPAxis::SelectablePart in the case of axes).
QCustomPlot uses an event propagation system that works the same as Qt's system. If your layerable doesn't reimplement the mousePressEvent or explicitly calls `event->ignore()` in its reimplementation, the event will be propagated to the next layerable in the stacking order.
Once a layerable has accepted the mousePressEvent, it is considered the mouse grabber and will receive all following calls to mouseMoveEvent or mouseReleaseEvent for this mouse interaction (a "mouse interaction" in this context ends with the release).
The default implementation does nothing except explicitly ignoring the event with `event->ignore()`.

See also

mouseMoveEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented in QCPAxis, QCPAxisRect, QCPTextElement, QCPColorScaleAxisRectPrivate, QCPColorScale, QCPPolarAxisRadial, and QCPPolarAxisAngular.

17.648.3.5 mouseReleaseEvent()

```
void QCPLayerable::mouseReleaseEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user releases the mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseMoveEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented in QCPAxis, QCPAxisRect, QCPTextElement, QCPColorScaleAxisRectPrivate, QCPColorScale, QCPPolarAxisRadial, and QCPPolarAxisAngular.

17.648.3.6 parentLayerable()

```
QCPLayerable * QCPLayerable::parentLayerable ( ) const  [inline]
```

Returns the parent layerable of this layerable. The parent layerable is used to provide visibility hierarchies in conjunction with the method realVisibility. This way, layerables only get drawn if their parent layerables are visible, too.
Note that a parent layerable is not necessarily also the QObject parent for memory management. Further, a layerable doesn't always have a parent layerable, so this function may return `nullptr`.
A parent layerable is set implicitly when placed inside layout elements and doesn't need to be set manually by the user.

17.648.3.7 realVisibility()

```
bool QCPLayerable::realVisibility ( ) const
```

Returns whether this layerable is visible, taking the visibility of the layerable parent and the visibility of this layerable's layer into account. This is the method that is consulted to decide whether a layerable shall be drawn or not.
If this layerable has a direct layerable parent (usually set via hierarchies implemented in subclasses, like in the case of QCPLayoutElement), this function returns true only if this layerable has its visibility set to true and the parent layerable's realVisibility returns true.

17.648.3.8 selectTest()

```
double QCPLayerable::selectTest (
            const QPointF & pos,
```

```
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

Reimplemented in QCPPolarGraph, QCPPolarAxisRadial, QCPPolarAxisAngular, QCPLayoutElement, QCPLayoutInset, QCPAxis, QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCPCurv QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat QCPAbstractLegendItem, QCPLegend, QCPTextElement, QCPGraph, QCPCurve, QCPBars, QCPStatisticalBox, QCPColorMap, QCPFinancial, QCPErrorBars, QCPItemStraightLine, QCPItemLine, QCPItemCurve, QCPItemRect, QCPItemText, QCPItemEllipse, QCPItemPixmap, QCPItemTracer, QCPItemBracket, QCPAbstractPlottable, and QCPAbstractItem.

17.648.3.9 setAntialiased()

```
void QCPLayerable::setAntialiased (
            bool enabled )
```

Sets whether this object will be drawn antialiased or not.
Note that antialiasing settings may be overridden by QCustomPlot::setAntialiasedElements and QCustomPlot::setNotAntialiasedEleme

17.648.3.10 setLayer() [1/2]

```
bool QCPLayerable::setLayer (
            const QString & layerName )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. Sets the layer of this layerable object by name
Returns true on success, i.e. if *layerName* is a valid layer name.

17.648.3.11 setLayer() [2/2]

```
bool QCPLayerable::setLayer (
            QCPLayer * layer )
```

Sets the *layer* of this layerable object. The object will be placed on top of the other objects already on *layer*.
If *layer* is 0, this layerable will not be on any layer and thus not appear in the plot (or interact/receive events).
Returns true if the layer of this layerable was successfully changed to *layer*.

17.648.3.12 setVisible()

```
void QCPLayerable::setVisible (
            bool on )
```

Sets the visibility of this layerable object. If an object is not visible, it will not be drawn on the QCustomPlot surface, and user interaction with it (e.g. click and selection) is not possible.

17.648.3.13 wheelEvent()

```
void QCPLayerable::wheelEvent (
            QWheelEvent * event )  [protected], [virtual]
```

This event gets called when the user turns the mouse scroll wheel while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`.
The `event->angleDelta()` indicates how far the mouse wheel was turned, which is usually +/- 120 for single rotation steps. However, if the mouse wheel is turned rapidly, multiple steps may accumulate to one event, making the delta larger. On the other hand, if the wheel has very smooth steps or none at all, the delta may be smaller.
The default implementation does nothing.

17.649.1 Detailed Description

The abstract base class for layouts.
This is an abstract base class for layout elements whose main purpose is to define the position and size of other child layout elements. In most cases, layouts don't draw anything themselves (but there are exceptions to this, e.g. QCPLegend).
QCPLayout derives from QCPLayoutElement, and thus can itself be nested in other layouts.
QCPLayout introduces a common interface for accessing and manipulating the child elements. Those functions are most notably elementCount, elementAt, takeAt, take, simplify, removeAt, remove and clear. Individual subclasses may add more functions to this interface which are more specialized to the form of the layout. For example, QCPLayoutGrid adds functions that take row and column indices to access cells of the layout grid more conveniently.
Since this is an abstract base class, you can't instantiate it directly. Rather use one of its subclasses like QCPLayoutGrid or QCPLayoutInset.
For a general introduction to the layout system, see the dedicated documentation page The Layout System.

17.649.2 Constructor & Destructor Documentation

17.649.2.1 QCPLayout()

```
QCPLayout::QCPLayout ( )  [explicit]
```

Creates an instance of QCPLayout and sets default values. Note that since QCPLayout is an abstract base class, it can't be instantiated directly.

17.649.3 Member Function Documentation

17.649.3.1 clear()

```
void QCPLayout::clear ( )
```

Removes and deletes all layout elements in this layout. Finally calls simplify to make sure all empty cells are collapsed.

See also

remove, removeAt

17.649.3.2 elementAt()

```
QCPLayoutElement * QCPLayout::elementAt (
            int index ) const  [pure virtual]
```

Returns the element in the cell with the given *index*. If *index* is invalid, returns `nullptr`.
Note that even if *index* is valid, the respective cell may be empty in some layouts (e.g. QCPLayoutGrid), so this function may return `nullptr` in those cases. You may use this function to check whether a cell is empty or not.

See also

elements, elementCount, takeAt

Implemented in QCPLayoutGrid, and QCPLayoutInset.

17.649.3.3 elementCount()

```
int QCPLayout::elementCount ( ) const  [pure virtual]
```

Returns the number of elements/cells in the layout.

See also

elements, elementAt

Implemented in QCPLayoutGrid, and QCPLayoutInset.

17.649.3.4 elements()

```
QList< QCPLayoutElement * > QCPLayout::elements (
            bool recursive ) const  [virtual]
```

Returns a list of all child elements in this layout element. If *recursive* is true, all sub-child elements are included in the list, too.

Warning

There may be `nullptr` entries in the returned list. For example, QCPLayoutGrid may have empty cells which yield `nullptr` at the respective index.

Reimplemented from QCPLayoutElement.
Reimplemented in QCPLayoutGrid.

17.649.3.5 remove()

```
bool QCPLayout::remove (
            QCPLayoutElement * element )
```

Removes and deletes the provided *element*. Returns true on success. If *element* is not in the layout, returns false.
This function internally uses takeAt to remove the element from the layout and then deletes the element. Note that some layouts don't remove the respective cell right away but leave an empty cell after successful removal of the layout element. To collapse empty cells, use simplify.

See also

removeAt, take

17.649.3.6 removeAt()

```
bool QCPLayout::removeAt (
            int index )
```

Removes and deletes the element at the provided *index*. Returns true on success. If *index* is invalid or points to an empty cell, returns false.
This function internally uses takeAt to remove the element from the layout and then deletes the returned element. Note that some layouts don't remove the respective cell right away but leave an empty cell after successful removal of the layout element. To collapse empty cells, use simplify.

See also

remove, takeAt

17.649.3.7 simplify()

```
void QCPLayout::simplify ( )  [virtual]
```

Simplifies the layout by collapsing empty cells. The exact behavior depends on subclasses, the default implementation does nothing.
Not all layouts need simplification. For example, QCPLayoutInset doesn't use explicit simplification while QCPLayoutGrid does.
Reimplemented in QCPLayoutGrid, and QCPLayoutInset.

17.649.3.8 sizeConstraintsChanged()

```
void QCPLayout::sizeConstraintsChanged ( ) const  [protected]
```

Subclasses call this method to report changed (minimum/maximum) size constraints.
If the parent of this layout is again a QCPLayout, forwards the call to the parent's sizeConstraintsChanged. If the parent is a QWidget (i.e. is the QCustomPlot::plotLayout of QCustomPlot), calls QWidget::updateGeometry, so if the QCustomPlot widget is inside a Qt QLayout, it may update itself and resize cells accordingly.

17.649.3.9 take()

```
bool QCPLayout::take (
            QCPLayoutElement * element )  [pure virtual]
```

Removes the specified *element* from the layout and returns true on success.
If the *element* isn't in this layout, returns false.
Note that some layouts don't remove the respective cell right away but leave an empty cell after successful removal of the layout element. To collapse empty cells, use simplify.

See also

takeAt

Implemented in QCPLayoutGrid, and QCPLayoutInset.

17.649.3.10 takeAt()

```
QCPLayoutElement * QCPLayout::takeAt (
            int index )  [pure virtual]
```

Removes the element with the given *index* from the layout and returns it.
If the *index* is invalid or the cell with that index is empty, returns `nullptr`.
Note that some layouts don't remove the respective cell right away but leave an empty cell after successful removal of the layout element. To collapse empty cells, use simplify.

See also

elementAt, take

Implemented in QCPLayoutGrid, and QCPLayoutInset.

17.649.3.11 update()

```
void QCPLayout::update (
            UpdatePhase phase )  [virtual]
```

If *phase* is upLayout, calls updateLayout, which subclasses may reimplement to reposition and resize their cells. Finally, the call is propagated down to all child QCPLayoutElements.
For details about this method and the update phases, see the documentation of QCPLayoutElement::update.
Reimplemented from QCPLayoutElement.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.650.1 Detailed Description

The abstract base class for all objects that form the layout system.
This is an abstract base class. As such, it can't be instantiated directly, rather use one of its subclasses.
A Layout element is a rectangular object which can be placed in layouts. It has an outer rect (QCPLayoutElement::outerRect) and an inner rect (QCPLayoutElement::rect). The difference between outer and inner rect is called its margin. The margin can either be set to automatic or manual (setAutoMargins) on a per-side basis. If a side is set to manual, that margin can be set explicitly with setMargins and will stay fixed at that value. If it's set to automatic, the layout element subclass will control the value itself (via calculateAutoMargin).
Layout elements can be placed in layouts (base class QCPLayout) like QCPLayoutGrid. The top level layout is reachable via QCustomPlot::plotLayout, and is a QCPLayoutGrid. Since QCPLayout itself derives from QCPLayoutElement, layouts can be nested.
Thus in QCustomPlot one can divide layout elements into two categories: The ones that are invisible by themselves, because they don't draw anything. Their only purpose is to manage the position and size of other layout elements. This category of layout elements usually use QCPLayout as base class. Then there is the category of layout elements which actually draw something. For example, QCPAxisRect, QCPLegend and QCPTextElement are of this category. This does not necessarily mean that the latter category can't have child layout elements. QCPLegend for instance, actually derives from QCPLayoutGrid and the individual legend items are child layout elements in the grid layout.

17.650.2 Member Enumeration Documentation

17.650.2.1 SizeConstraintRect

`enum QCPLayoutElement::SizeConstraintRect`

Defines to which rect of a layout element the size constraints that can be set via setMinimumSize and setMaximumSize apply. The outer rect (outerRect) includes the margins (e.g. in the case of a QCPAxisRect the axis labels), whereas the inner rect (rect) does not.

See also

setSizeConstraintRect

Enumerator

scrInnerRect	Minimum/Maximum size constraints apply to inner rect.
scrOuterRect	Minimum/Maximum size constraints apply to outer rect, thus include layout element margins.

17.650.2.2 UpdatePhase

`enum QCPLayoutElement::UpdatePhase`

Defines the phases of the update process, that happens just before a replot. At each phase, update is called with the according UpdatePhase value.

Enumerator

upPreparation	Phase used for any type of preparation that needs to be done before margin calculation and layout.
upMargins	Phase in which the margins are calculated and set.
upLayout	Final phase in which the layout system places the rects of the elements.

17.650.3 Constructor & Destructor Documentation

17.650.3.1 QCPLayoutElement()

```
QCPLayoutElement::QCPLayoutElement (
            QCustomPlot * parentPlot = nullptr )  [explicit]
```

Creates an instance of QCPLayoutElement and sets default values.

17.650.4 Member Function Documentation

17.650.4.1 applyDefaultAntialiasingHint()

```
virtual void QCPLayoutElement::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [inline], [protected], [virtual]
```

Implements QCPLayerable.

17.650.4.2 draw()

```
virtual void QCPLayoutElement::draw (
            QCPPainter * painter )  [inline], [protected], [virtual]
```

Implements QCPLayerable.

17.650.4.3 elements()

```
QList< QCPLayoutElement * > QCPLayoutElement::elements (
            bool recursive ) const  [virtual]
```

Returns a list of all child elements in this layout element. If *recursive* is true, all sub-child elements are included in the list, too.

Warning

There may be `nullptr` entries in the returned list. For example, QCPLayoutGrid may have empty cells which yield `nullptr` at the respective index.

Reimplemented in QCPLayout, QCPLayoutGrid, QCPAxisRect, and QCPPolarAxisAngular.

17.650.4.4 layout()

```
QCPLayout * QCPLayoutElement::layout ( ) const  [inline]
```

Returns the parent layout of this layout element.

17.650.4.5 maximumOuterSizeHint()

```
QSize QCPLayoutElement::maximumOuterSizeHint ( ) const  [virtual]
```

Returns the suggested maximum size this layout element (the outerRect) may be expanded to, if no manual maximum size is set.
if a maximum size (setMaximumSize) was not set manually, parent layouts use the returned size (usually indirectly through QCPLayout::getFinalMaximumOuterSize) to determine the maximum allowed size of this layout element.
A manual maximum size is considered set if it is smaller than Qt's `QWIDGETSIZE_MAX`.
The default implementation simply returns `QWIDGETSIZE_MAX` for both width and height, implying no suggested maximum size. Reimplementations may use their detailed knowledge about the layout element's content to provide size hints.
Reimplemented in QCPLayoutGrid, and QCPTextElement.

17.650.4.6 minimumOuterSizeHint()

```
QSize QCPLayoutElement::minimumOuterSizeHint ( ) const  [virtual]
```

Returns the suggested minimum size this layout element (the outerRect) may be compressed to, if no manual minimum size is set.
if a minimum size (setMinimumSize) was not set manually, parent layouts use the returned size (usually indirectly through QCPLayout::getFinalMinimumOuterSize) to determine the minimum allowed size of this layout element.
A manual minimum size is considered set if it is non-zero.
The default implementation simply returns the sum of the horizontal margins for the width and the sum of the vertical margins for the height. Reimplementations may use their detailed knowledge about the layout element's content to provide size hints.
Reimplemented in QCPLayoutGrid, QCPPlottableLegendItem, QCPTextElement, and QCPPolarLegendItem.

17.650.4.7 outerRect()

```
QRect QCPLayoutElement::outerRect ( ) const  [inline]
```

Returns the outer rect of this layout element. The outer rect is the inner rect expanded by the margins (setMargins, setAutoMargins). The outer rect is used (and set via setOuterRect) by the parent QCPLayout to control the size of this layout element.

See also

rect

17.650.4.8 parentPlotInitialized()

```
void QCPLayoutElement::parentPlotInitialized (
            QCustomPlot * parentPlot )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.650.4.9 rect()

```
QRect QCPLayoutElement::rect ( ) const  [inline]
```

Returns the inner rect of this layout element. The inner rect is the outer rect (outerRect, setOuterRect) shrinked by the margins (setMargins, setAutoMargins).

In some cases, the area between outer and inner rect is left blank. In other cases the margin area is used to display peripheral graphics while the main content is in the inner rect. This is where automatic margin calculation becomes interesting because it allows the layout element to adapt the margins to the peripheral graphics it wants to draw. For example, QCPAxisRect draws the axis labels and tick labels in the margin area, thus needs to adjust the margins (if setAutoMargins is enabled) according to the space required by the labels of the axes.

See also

outerRect

17.650.4.10 selectTest()

```
double QCPLayoutElement::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Layout elements are sensitive to events inside their outer rect. If *pos* is within the outer rect, this method returns a value corresponding to 0.99 times the parent plot's selection tolerance. However, layout elements are not selectable by default. So if *onlySelectable* is true, -1.0 is returned.

See QCPLayerable::selectTest for a general explanation of this virtual method.

QCPLayoutElement subclasses may reimplement this method to provide more specific selection test behaviour.

Reimplemented from QCPLayerable.

Reimplemented in QCPPolarAxisAngular, QCPLayoutInset, QCPAbstractLegendItem, QCPLegend, and QCPTextElement.

17.650.4.11 setAutoMargins()

```
void QCPLayoutElement::setAutoMargins (
            QCP::MarginSides sides )
```

Sets on which sides the margin shall be calculated automatically. If a side is calculated automatically, a minimum margin value may be provided with setMinimumMargins. If a side is set to be controlled manually, the value may be specified with setMargins.

Margin sides that are under automatic control may participate in a QCPMarginGroup (see setMarginGroup), to synchronize (align) it with other layout elements in the plot.

See also

setMinimumMargins, setMargins, QCP::MarginSide

17.650.4.12 setMarginGroup()

```
void QCPLayoutElement::setMarginGroup (
            QCP::MarginSides sides,
            QCPMarginGroup * group )
```

Sets the margin *group* of the specified margin *sides*.

Margin groups allow synchronizing specified margins across layout elements, see the documentation of QCPMarginGroup.

To unset the margin group of *sides*, set *group* to `nullptr`.

Note that margin groups only work for margin sides that are set to automatic (setAutoMargins).

See also

QCP::MarginSide

17.650.4.13 setMargins()

```
void QCPLayoutElement::setMargins (
            const QMargins & margins )
```

Sets the margins of this layout element. If setAutoMargins is disabled for some or all sides, this function is used to manually set the margin on those sides. Sides that are still set to be handled automatically are ignored and may have any value in *margins*.
The margin is the distance between the outer rect (controlled by the parent layout via setOuterRect) and the inner rect (which usually contains the main content of this layout element).

See also

setAutoMargins

17.650.4.14 setMaximumSize() [1/2]

```
void QCPLayoutElement::setMaximumSize (
            const QSize & size )
```

Sets the maximum size of this layout element. A parent layout tries to respect the *size* here by changing row/column sizes in the layout accordingly.
Whether this constraint applies to the inner or the outer rect can be specified with setSizeConstraintRect (see rect and outerRect).

17.650.4.15 setMaximumSize() [2/2]

```
void QCPLayoutElement::setMaximumSize (
            int width,
            int height )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the maximum size of this layout element.
Whether this constraint applies to the inner or the outer rect can be specified with setSizeConstraintRect (see rect and outerRect).

17.650.4.16 setMinimumMargins()

```
void QCPLayoutElement::setMinimumMargins (
            const QMargins & margins )
```

If setAutoMargins is enabled on some or all margins, this function is used to provide minimum values for those margins.
The minimum values are not enforced on margin sides that were set to be under manual control via setAutoMargins.

See also

setAutoMargins

17.650.4.17 setMinimumSize() [1/2]

```
void QCPLayoutElement::setMinimumSize (
            const QSize & size )
```

Sets the minimum size of this layout element. A parent layout tries to respect the *size* here by changing row/column sizes in the layout accordingly.
If the parent layout size is not sufficient to satisfy all minimum size constraints of its child layout elements, the layout may set a size that is actually smaller than *size*. QCustomPlot propagates the layout's size constraints to the outside by setting its own minimum QWidget size accordingly, so violations of *size* should be exceptions.
Whether this constraint applies to the inner or the outer rect can be specified with setSizeConstraintRect (see rect and outerRect).

17.650.4.18 setMinimumSize() [2/2]

```
void QCPLayoutElement::setMinimumSize (
            int width,
            int height )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the minimum size of this layout element.
Whether this constraint applies to the inner or the outer rect can be specified with setSizeConstraintRect (see rect and outerRect).

17.650.4.19 setOuterRect()

```
void QCPLayoutElement::setOuterRect (
            const QRect & rect )
```

Sets the outer rect of this layout element. If the layout element is inside a layout, the layout sets the position and size of this layout element using this function.
Calling this function externally has no effect, since the layout will overwrite any changes to the outer rect upon the next replot.
The layout element will adapt its inner rect by applying the margins inward to the outer rect.

See also

rect

17.650.4.20 setSizeConstraintRect()

```
void QCPLayoutElement::setSizeConstraintRect (
            SizeConstraintRect constraintRect )
```

Sets to which rect of a layout element the size constraints apply. Size constraints can be set via setMinimumSize and setMaximumSize.
The outer rect (outerRect) includes the margins (e.g. in the case of a QCPAxisRect the axis labels), whereas the inner rect (rect) does not.

See also

setMinimumSize, setMaximumSize

17.650.4.21 update()

```
void QCPLayoutElement::update (
            UpdatePhase phase ) [virtual]
```

Updates the layout element and sub-elements. This function is automatically called before every replot by the parent layout element. It is called multiple times, once for every UpdatePhase. The phases are run through in the order of the enum values. For details about what happens at the different phases, see the documentation of UpdatePhase.
Layout elements that have child elements should call the update method of their child elements, and pass the current *phase* unchanged.
The default implementation executes the automatic margin mechanism in the upMargins phase. Subclasses should make sure to call the base class implementation.
Reimplemented in QCPLayout, QCPAxisRect, QCPColorScaleAxisRectPrivate, QCPColorScale, and QCPPolarAxisAngular.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.651.1 Detailed Description

A layout that arranges child elements in a grid.
Elements are laid out in a grid with configurable stretch factors (setColumnStretchFactor, setRowStretchFactor) and spacing (setColumnSpacing, setRowSpacing).
Elements can be added to cells via addElement. The grid is expanded if the specified row or column doesn't exist yet. Whether a cell contains a valid layout element can be checked with hasElement, that element can be retrieved with element. If rows and columns that only have empty cells shall be removed, call simplify. Removal of elements is either done by just adding the element to a different layout or by using the QCPLayout interface take or remove.
If you use addElement(QCPLayoutElement*) without explicit parameters for *row* and *column*, the grid layout will choose the position according to the current setFillOrder and the wrapping (setWrap).
Row and column insertion can be performed with insertRow and insertColumn.

17.651.2 Member Enumeration Documentation

17.651.2.1 FillOrder

enum QCPLayoutGrid::FillOrder

Defines in which direction the grid is filled when using addElement(QCPLayoutElement*). The column/row at which wrapping into the next row/column occurs can be specified with setWrap.

See also

setFillOrder

Enumerator

foRowsFirst	Rows are filled first, and a new element is wrapped to the next column if the row count would exceed setWrap.
foColumnsFirst	Columns are filled first, and a new element is wrapped to the next row if the column count would exceed setWrap.

17.651.3 Constructor & Destructor Documentation

17.651.3.1 QCPLayoutGrid()

QCPLayoutGrid::QCPLayoutGrid ( ) [explicit]

Creates an instance of QCPLayoutGrid and sets default values.

17.651.4 Member Function Documentation

17.651.4.1 addElement() [1/2]

```
bool QCPLayoutGrid::addElement (
            int row,
            int column,
            QCPLayoutElement * element )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Adds the *element* to cell with *row* and *column*. If *element* is already in a layout, it is first removed from there. If *row* or *column* don't exist yet, the layout is expanded accordingly.

Returns true if the element was added successfully, i.e. if the cell at *row* and *column* didn't already have an element.

Use the overload of this method without explicit row/column index to place the element according to the configured fill order and wrapping settings.

See also

element, hasElement, take, remove

17.651.4.2 addElement() [2/2]

```
bool QCPLayoutGrid::addElement (
            QCPLayoutElement * element )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Adds the *element* to the next empty cell according to the current fill order (setFillOrder) and wrapping (setWrap). If *element* is already in a layout, it is first removed from there. If necessary, the layout is expanded to hold the new element.

Returns true if the element was added successfully.

See also

setFillOrder, setWrap, element, hasElement, take, remove

17.651.4.3 columnCount()

```
int QCPLayoutGrid::columnCount ( ) const  [inline]
```
Returns the number of columns in the layout.

See also

rowCount

17.651.4.4 element()

```
QCPLayoutElement * QCPLayoutGrid::element (
            int row,
            int column ) const
```
Returns the element in the cell in *row* and *column*.
Returns `nullptr` if either the row/column is invalid or if the cell is empty. In those cases, a qDebug message is printed. To check whether a cell exists and isn't empty, use hasElement.

See also

addElement, hasElement

17.651.4.5 elementAt()

```
QCPLayoutElement * QCPLayoutGrid::elementAt (
            int index ) const  [virtual]
```
\seebaseclassmethod
Note that the association of the linear *index* to the row/column based cells depends on the current setting of setFillOrder.

See also

rowColToIndex

Implements QCPLayout.

17.651.4.6 elementCount()

```
virtual int QCPLayoutGrid::elementCount ( ) const  [inline], [virtual]
```
Returns the number of elements/cells in the layout.

See also

elements, elementAt

Implements QCPLayout.

17.651.4.7 elements()

```
QList< QCPLayoutElement * > QCPLayoutGrid::elements (
            bool recursive ) const  [virtual]
```
Returns a list of all child elements in this layout element. If *recursive* is true, all sub-child elements are included in the list, too.

Warning

There may be `nullptr` entries in the returned list. For example, QCPLayoutGrid may have empty cells which yield `nullptr` at the respective index.

Reimplemented from QCPLayout.

17.651.4.8 expandTo()

```
void QCPLayoutGrid::expandTo (
            int newRowCount,
            int newColumnCount )
```

Expands the layout to have *newRowCount* rows and *newColumnCount* columns. So the last valid row index will be *newRowCount-1*, the last valid column index will be *newColumnCount-1*.
If the current column/row count is already larger or equal to *newColumnCount/newRowCount,* this function does nothing in that dimension.
Newly created cells are empty, new rows and columns have the stretch factor 1.
Note that upon a call to addElement, the layout is expanded automatically to contain the specified row and column, using this function.

See also

simplify

17.651.4.9 hasElement()

```
bool QCPLayoutGrid::hasElement (
            int row,
            int column )
```

Returns whether the cell at *row* and *column* exists and contains a valid element, i.e. isn't empty.

See also

element

17.651.4.10 indexToRowCol()

```
void QCPLayoutGrid::indexToRowCol (
            int index,
            int & row,
            int & column ) const
```

Converts the linear index to row and column indices and writes the result to *row* and *column*.
The way the cells are indexed depends on setFillOrder. If it is foRowsFirst, the indices increase left to right and then top to bottom. If it is foColumnsFirst, the indices increase top to bottom and then left to right.
If there are no cells (i.e. column or row count is zero), sets *row* and *column* to -1.
For the retrieved *row* and *column* to be valid, the passed *index* must be valid itself, i.e. greater or equal to zero and smaller than the current elementCount.

See also

rowColToIndex

17.651.4.11 insertColumn()

```
void QCPLayoutGrid::insertColumn (
            int newIndex )
```

Inserts a new column with empty cells at the column index *newIndex*. Valid values for *newIndex* range from 0 (inserts a column at the left) to *columnCount* (appends a column at the right).

See also

insertRow

17.651.4.12 insertRow()

```
void QCPLayoutGrid::insertRow (
            int newIndex )
```

Inserts a new row with empty cells at the row index *newIndex*. Valid values for *newIndex* range from 0 (inserts a row at the top) to *rowCount* (appends a row at the bottom).

See also

insertColumn

17.651.4.13 maximumOuterSizeHint()

```
QSize QCPLayoutGrid::maximumOuterSizeHint ( ) const  [virtual]
```

Returns the suggested maximum size this layout element (the outerRect) may be expanded to, if no manual maximum size is set.
if a maximum size (setMaximumSize) was not set manually, parent layouts use the returned size (usually indirectly through QCPLayout::getFinalMaximumOuterSize) to determine the maximum allowed size of this layout element.
A manual maximum size is considered set if it is smaller than Qt's QWIDGETSIZE_MAX.
The default implementation simply returns QWIDGETSIZE_MAX for both width and height, implying no suggested maximum size. Reimplementations may use their detailed knowledge about the layout element's content to provide size hints.
Reimplemented from QCPLayoutElement.

17.651.4.14 minimumOuterSizeHint()

```
QSize QCPLayoutGrid::minimumOuterSizeHint ( ) const  [virtual]
```

Returns the suggested minimum size this layout element (the outerRect) may be compressed to, if no manual minimum size is set.
if a minimum size (setMinimumSize) was not set manually, parent layouts use the returned size (usually indirectly through QCPLayout::getFinalMinimumOuterSize) to determine the minimum allowed size of this layout element.
A manual minimum size is considered set if it is non-zero.
The default implementation simply returns the sum of the horizontal margins for the width and the sum of the vertical margins for the height. Reimplementations may use their detailed knowledge about the layout element's content to provide size hints.
Reimplemented from QCPLayoutElement.

17.651.4.15 rowColToIndex()

```
int QCPLayoutGrid::rowColToIndex (
            int row,
            int column ) const
```

Converts the given *row* and *column* to the linear index used by some methods of QCPLayoutGrid and QCPLayout.
The way the cells are indexed depends on setFillOrder. If it is foRowsFirst, the indices increase left to right and then top to bottom. If it is foColumnsFirst, the indices increase top to bottom and then left to right.
For the returned index to be valid, *row* and *column* must be valid indices themselves, i.e. greater or equal to zero and smaller than the current rowCount/ columnCount.

See also

indexToRowCol

17.651.4.16 rowCount()

```
int QCPLayoutGrid::rowCount ( ) const  [inline]
```

Returns the number of rows in the layout.

See also

columnCount

17.651.4.17 setColumnSpacing()

```
void QCPLayoutGrid::setColumnSpacing (
            int pixels )
```

Sets the gap that is left blank between columns to *pixels*.

See also

setRowSpacing

17.651.4.18 setColumnStretchFactor()

```
void QCPLayoutGrid::setColumnStretchFactor (
            int column,
            double factor )
```

Sets the stretch *factor* of *column*.
Stretch factors control the relative sizes of rows and columns. Cells will not be resized beyond their minimum and maximum widths/heights, regardless of the stretch factor. (see QCPLayoutElement::setMinimumSize, QCPLayoutElement::setMaximumSize, QCPLayoutElement::setSizeConstraintRect.)
The default stretch factor of newly created rows/columns is 1.

See also

setColumnStretchFactors, setRowStretchFactor

17.651.4.19 setColumnStretchFactors()

```
void QCPLayoutGrid::setColumnStretchFactors (
            const QList< double > & factors )
```

Sets the stretch *factors* of all columns. *factors* must have the size columnCount.
Stretch factors control the relative sizes of rows and columns. Cells will not be resized beyond their minimum and maximum widths/heights, regardless of the stretch factor. (see QCPLayoutElement::setMinimumSize, QCPLayoutElement::setMaximumSize, QCPLayoutElement::setSizeConstraintRect.)
The default stretch factor of newly created rows/columns is 1.

See also

setColumnStretchFactor, setRowStretchFactors

17.651.4.20 setFillOrder()

```
void QCPLayoutGrid::setFillOrder (
            FillOrder order,
            bool rearrange = true )
```

Sets the filling order and wrapping behaviour that is used when adding new elements with the method addElement(QCPLayoutElement*).
The specified *order* defines whether rows or columns are filled first. Using setWrap, you can control at which row/column count wrapping into the next column/row will occur. If you set it to zero, no wrapping will ever occur. Changing the fill order also changes the meaning of the linear index used e.g. in elementAt and takeAt. The default fill order for QCPLayoutGrid is foColumnsFirst.
If you want to have all current elements arranged in the new order, set *rearrange* to true. The elements will be rearranged in a way that tries to preserve their linear index. However, empty cells are skipped during build-up of the new cell order, which shifts the succeeding element's index. The rearranging is performed even if the specified *order* is already the current fill order. Thus this method can be used to re-wrap the current elements.
If *rearrange* is false, the current element arrangement is not changed, which means the linear indexes change (because the linear index is dependent on the fill order).
Note that the method addElement(int row, int column, QCPLayoutElement *element) with explicitly stated row and column is not subject to wrapping and can place elements even beyond the specified wrapping point.

See also

setWrap, addElement(QCPLayoutElement*)

17.651.4.21 setRowSpacing()

```
void QCPLayoutGrid::setRowSpacing (
            int pixels )
```

Sets the gap that is left blank between rows to *pixels*.

See also

setColumnSpacing

17.651.4.22 setRowStretchFactor()

```
void QCPLayoutGrid::setRowStretchFactor (
            int row,
            double factor )
```

Sets the stretch *factor* of *row*.
Stretch factors control the relative sizes of rows and columns. Cells will not be resized beyond their minimum and maximum widths/heights, regardless of the stretch factor. (see QCPLayoutElement::setMinimumSize, QCPLayoutElement::setMaximumSize, QCPLayoutElement::setSizeConstraintRect.)
The default stretch factor of newly created rows/columns is 1.

See also

setColumnStretchFactors, setRowStretchFactor

17.651.4.23 setRowStretchFactors()

```
void QCPLayoutGrid::setRowStretchFactors (
            const QList< double > & factors )
```

Sets the stretch *factors* of all rows. *factors* must have the size rowCount.
Stretch factors control the relative sizes of rows and columns. Cells will not be resized beyond their minimum and maximum widths/heights, regardless of the stretch factor. (see QCPLayoutElement::setMinimumSize, QCPLayoutElement::setMaximumSize, QCPLayoutElement::setSizeConstraintRect.)
The default stretch factor of newly created rows/columns is 1.

See also

setRowStretchFactor, setColumnStretchFactors

17.651.4.24 setWrap()

```
void QCPLayoutGrid::setWrap (
            int count )
```

Sets the maximum number of columns or rows that are used, before new elements added with addElement(QCPLayoutElement*) will start to fill the next row or column, respectively. It depends on setFillOrder, whether rows or columns are wrapped.
If *count* is set to zero, no wrapping will ever occur.
If you wish to re-wrap the elements currently in the layout, call setFillOrder with *rearrange* set to true (the actual fill order doesn't need to be changed for the rearranging to be done).
Note that the method addElement(int row, int column, QCPLayoutElement *element) with explicitly stated row and column is not subject to wrapping and can place elements even beyond the specified wrapping point.

See also

setFillOrder

17.651.4.25 simplify()

```
void QCPLayoutGrid::simplify ( )  [virtual]
```

Simplifies the layout by collapsing rows and columns which only contain empty cells.
Reimplemented from QCPLayout.

17.651.4.26 take()

```
bool QCPLayoutGrid::take (
            QCPLayoutElement * element )  [virtual]
```

Removes the specified *element* from the layout and returns true on success.
If the *element* isn't in this layout, returns false.
Note that some layouts don't remove the respective cell right away but leave an empty cell after successful removal of the layout element. To collapse empty cells, use simplify.

See also

takeAt

Implements QCPLayout.

17.651.4.27 takeAt()

```
QCPLayoutElement * QCPLayoutGrid::takeAt (
            int index )  [virtual]
```

\seebaseclassmethod
Note that the association of the linear *index* to the row/column based cells depends on the current setting of setFillOrder.

17.652.1 Detailed Description

A layout that places child elements aligned to the border or arbitrarily positioned.
Elements are placed either aligned to the border or at arbitrary position in the area of the layout. Which placement applies is controlled with the InsetPlacement (setInsetPlacement).
Elements are added via addElement(QCPLayoutElement *element, Qt::Alignment alignment) or addElement(QCPLayoutElement *ele
If the first method is used, the inset placement will default to ipBorderAligned and the element will be aligned according to the *alignment* parameter. The second method defaults to ipFree and allows placing elements at arbitrary position and size, defined by *rect*.
The alignment or rect can be set via setInsetAlignment or setInsetRect, respectively.
This is the layout that every QCPAxisRect has as QCPAxisRect::insetLayout.

17.652.2 Member Enumeration Documentation

17.652.2.1 InsetPlacement

`enum QCPLayoutInset::InsetPlacement`
Defines how the placement and sizing is handled for a certain element in a QCPLayoutInset.

Enumerator

ipFree	The element may be positioned/sized arbitrarily, see setInsetRect.
ipBorderAligned	The element is aligned to one of the layout sides, see setInsetAlignment.

17.652.3 Constructor & Destructor Documentation

17.652.3.1 QCPLayoutInset()

```
QCPLayoutInset::QCPLayoutInset ( )  [explicit]
```

Creates an instance of QCPLayoutInset and sets default values.

17.652.4 Member Function Documentation

17.652.4.1 addElement() [1/2]

```
void QCPLayoutInset::addElement (
            QCPLayoutElement * element,
            const QRectF & rect )
```

Adds the specified *element* to the layout as an inset with free positioning/sizing (setInsetAlignment is initialized with ipFree). The position and size is set to *rect*.
rect is given in fractions of the whole inset layout rect. So an inset with rect (0, 0, 1, 1) will span the entire layout. An inset with rect (0.6, 0.1, 0.35, 0.35) will be in the top right corner of the layout, with 35% width and height of the parent layout.

See also

addElement(QCPLayoutElement *element, Qt::Alignment alignment)

17.652.4.2 addElement() [2/2]

```
void QCPLayoutInset::addElement (
            QCPLayoutElement * element,
            Qt::Alignment alignment )
```

Adds the specified *element* to the layout as an inset aligned at the border (setInsetAlignment is initialized with ipBorderAligned). The alignment is set to *alignment*.
alignment is an or combination of the following alignment flags: Qt::AlignLeft, Qt::AlignHCenter, Qt::AlighRight, Qt::AlignTop, Qt::AlignVCenter, Qt::AlignBottom. Any other alignment flags will be ignored.

See also

addElement(QCPLayoutElement *element, const QRectF &rect)

17.652.4.3 elementAt()

```
QCPLayoutElement * QCPLayoutInset::elementAt (
            int index ) const  [virtual]
```

Returns the element in the cell with the given *index*. If *index* is invalid, returns `nullptr`.
Note that even if *index* is valid, the respective cell may be empty in some layouts (e.g. QCPLayoutGrid), so this function may return `nullptr` in those cases. You may use this function to check whether a cell is empty or not.

See also

elements, elementCount, takeAt

Implements QCPLayout.

17.652.4.4 elementCount()

```
int QCPLayoutInset::elementCount ( ) const  [virtual]
```
Returns the number of elements/cells in the layout.

See also

elements, elementAt

Implements QCPLayout.

17.652.4.5 insetAlignment()

```
Qt::Alignment QCPLayoutInset::insetAlignment (
            int index ) const
```
Returns the alignment of the element with the specified *index*. The alignment only has a meaning, if the inset placement (setInsetPlacement) is ipBorderAligned.

17.652.4.6 insetPlacement()

```
QCPLayoutInset::InsetPlacement QCPLayoutInset::insetPlacement (
            int index ) const
```
Returns the placement type of the element with the specified *index*.

17.652.4.7 insetRect()

```
QRectF QCPLayoutInset::insetRect (
            int index ) const
```
Returns the rect of the element with the specified *index*. The rect only has a meaning, if the inset placement (setInsetPlacement) is ipFree.

17.652.4.8 selectTest()

```
double QCPLayoutInset::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```
The inset layout is sensitive to events only at areas where its (visible) child elements are sensitive. If the selectTest method of any of the child elements returns a positive number for *pos*, this method returns a value corresponding to 0.99 times the parent plot's selection tolerance. The inset layout is not selectable itself by default. So if *onlySelectable* is true, -1.0 is returned.
See QCPLayerable::selectTest for a general explanation of this virtual method.
Reimplemented from QCPLayoutElement.

17.652.4.9 setInsetAlignment()

```
void QCPLayoutInset::setInsetAlignment (
            int index,
            Qt::Alignment alignment )
```
If the inset placement (setInsetPlacement) is ipBorderAligned, this function is used to set the alignment of the element with the specified *index* to *alignment*.
alignment is an or combination of the following alignment flags: Qt::AlignLeft, Qt::AlignHCenter, Qt::AlighRight, Qt::AlignTop, Qt::AlignVCenter, Qt::AlignBottom. Any other alignment flags will be ignored.

17.652.4.10 setInsetPlacement()

```
void QCPLayoutInset::setInsetPlacement (
            int index,
            QCPLayoutInset::InsetPlacement placement )
```
Sets the inset placement type of the element with the specified *index* to *placement*.

See also

InsetPlacement

17.652.4.11 setInsetRect()

```
void QCPLayoutInset::setInsetRect (
            int index,
            const QRectF & rect )
```

If the inset placement (setInsetPlacement) is ipFree, this function is used to set the position and size of the element with the specified *index* to *rect*.
rect is given in fractions of the whole inset layout rect. So an inset with rect (0, 0, 1, 1) will span the entire layout. An inset with rect (0.6, 0.1, 0.35, 0.35) will be in the top right corner of the layout, with 35% width and height of the parent layout.
Note that the minimum and maximum sizes of the embedded element (QCPLayoutElement::setMinimumSize, QCPLayoutElement::setMaximumSize) are enforced.

17.652.4.12 simplify()

```
void QCPLayoutInset::simplify ( )  [inline], [virtual]
```

The QCPInsetLayout does not need simplification since it can never have empty cells due to its linear index structure. This method does nothing.
Reimplemented from QCPLayout.

17.652.4.13 take()

```
bool QCPLayoutInset::take (
            QCPLayoutElement * element )  [virtual]
```

Removes the specified *element* from the layout and returns true on success.
If the *element* isn't in this layout, returns false.
Note that some layouts don't remove the respective cell right away but leave an empty cell after successful removal of the layout element. To collapse empty cells, use simplify.

See also

takeAt

Implements QCPLayout.

17.652.4.14 takeAt()

```
QCPLayoutElement * QCPLayoutInset::takeAt (
            int index )  [virtual]
```

Removes the element with the given *index* from the layout and returns it.
If the *index* is invalid or the cell with that index is empty, returns `nullptr`.
Note that some layouts don't remove the respective cell right away but leave an empty cell after successful removal of the layout element. To collapse empty cells, use simplify.

17.653.1 Detailed Description

Manages a legend inside a QCustomPlot.
A legend is a small box somewhere in the plot which lists plottables with their name and icon.
A legend is populated with legend items by calling QCPAbstractPlottable::addToLegend on the plottable, for which a legend item shall be created. In the case of the main legend (QCustomPlot::legend), simply adding plottables to the plot while QCustomPlot::setAutoAddPlottableToLegend is set to true (the default) creates corresponding legend items. The legend item associated with a certain plottable can be removed with QCPAbstractPlottable::removeFromLegend. However, QCPLegend also offers an interface to add and manipulate legend items directly: item, itemWithPlottable, itemCount, addItem, removeItem, etc.
Since QCPLegend derives from QCPLayoutGrid, it can be placed in any position a QCPLayoutElement may be positioned. The legend items are themselves QCPLayoutElements which are placed in the grid layout of the legend. QCPLegend only adds an interface specialized for handling child elements of type QCPAbstractLegendItem, as mentioned above. In principle, any other layout elements may also be added to a legend via the normal QCPLayoutGrid interface. See the special page about The Layout System for examples on how to add other elements to the legend and move it outside the axis rect.
Use the methods setFillOrder and setWrap inherited from QCPLayoutGrid to control in which order (column first or row first) the legend is filled up when calling addItem, and at which column or row wrapping occurs. The default fill order for legends is foRowsFirst.
By default, every QCustomPlot has one legend (QCustomPlot::legend) which is placed in the inset layout of the main axis rect (QCPAxisRect::insetLayout). To move the legend to another position inside the axis rect, use the methods of the QCPLayoutInset. To move the legend outside of the axis rect, place it anywhere else with the QCPLayout/ QCPLayoutElement interface.

17.653.2 Member Enumeration Documentation

17.653.2.1 SelectablePart

`enum QCPLegend::SelectablePart`
Defines the selectable parts of a legend

See also

setSelectedParts, setSelectableParts

Enumerator

spNone	`0x000` None
spLegendBox	`0x001` The legend box (frame)
spItems	`0x002` Legend items individually (see selectedItems)

17.653.3 Constructor & Destructor Documentation

17.653.3.1 QCPLegend()

```
QCPLegend::QCPLegend ( )  [explicit]
```

Constructs a new QCPLegend instance with default values.
Note that by default, QCustomPlot already contains a legend ready to be used as QCustomPlot::legend

17.653.4 Member Function Documentation

17.653.4.1 addItem()

```
bool QCPLegend::addItem (
            QCPAbstractLegendItem * item )
```

Adds *item* to the legend, if it's not present already. The element is arranged according to the current fill order (setFillOrder) and wrapping (setWrap).
Returns true on sucess, i.e. if the item wasn't in the list already and has been successfuly added.
The legend takes ownership of the item.

See also

removeItem, item, hasItem

17.653.4.2 applyDefaultAntialiasingHint()

```
void QCPLegend::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Reimplemented from QCPLayoutElement.

17.653.4.3 clearItems()

```
void QCPLegend::clearItems ( )
```

Removes all items from the legend.

17.653.4.4 deselectEvent()

```
void QCPLegend::deselectEvent (
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.653.4.5 draw()

```
void QCPLegend::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Reimplemented from QCPLayoutElement.

17.653.4.6 hasItem()

```
bool QCPLegend::hasItem (
            QCPAbstractLegendItem * item ) const
```

Returns whether the legend contains *item*.

See also

hasItemWithPlottable

17.653.4.7 hasItemWithPlottable()

```
bool QCPLegend::hasItemWithPlottable (
            const QCPAbstractPlottable * plottable ) const
```

Returns whether the legend contains a QCPPlottableLegendItem which is associated with *plottable* (e.g. a QCPGraph*). If such an item isn't in the legend, returns false.

See also

itemWithPlottable

17.653.4.8 item()

```
QCPAbstractLegendItem * QCPLegend::item (
            int index ) const
```

Returns the item with index *i*. If non-legend items were added to the legend, and the element at the specified cell index is not a QCPAbstractLegendItem, returns `nullptr`.
Note that the linear index depends on the current fill order (setFillOrder).

See also

itemCount, addItem, itemWithPlottable

17.653.4.9 itemCount()

```
int QCPLegend::itemCount ( ) const
```

Returns the number of items currently in the legend. It is identical to the base class QCPLayoutGrid::elementCount(), and unlike the other "item" interface methods of QCPLegend, doesn't only address elements which can be cast to QCPAbstractLegendItem.
Note that if empty cells are in the legend (e.g. by calling methods of the QCPLayoutGrid base class which allows creating empty cells), they are included in the returned count.

See also

item

17.653.4.10 itemWithPlottable()

```
QCPPlottableLegendItem * QCPLegend::itemWithPlottable (
            const QCPAbstractPlottable * plottable ) const
```

Returns the QCPPlottableLegendItem which is associated with *plottable* (e.g. a QCPGraph*). If such an item isn't in the legend, returns `nullptr`.

See also

hasItemWithPlottable

17.653.4.11 parentPlotInitialized()

```
void QCPLegend::parentPlotInitialized (
            QCustomPlot * parentPlot )  [protected], [virtual]
```

Reimplemented from QCPLayoutElement.

17.653.4.12 removeItem() [1/2]

```
bool QCPLegend::removeItem (
            int index )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Removes the item with the specified *index* from the legend and deletes it.
After successful removal, the legend is reordered according to the current fill order (setFillOrder) and wrapping (setWrap), so no empty cell remains where the removed *item* was. If you don't want this, rather use the raw element interface of QCPLayoutGrid.
Returns true, if successful. Unlike QCPLayoutGrid::removeAt, this method only removes elements derived from QCPAbstractLegendItem.

See also

itemCount, clearItems

17.653.4.13 removeItem() [2/2]

```
bool QCPLegend::removeItem (
            QCPAbstractLegendItem * item )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Removes *item* from the legend and deletes it.
After successful removal, the legend is reordered according to the current fill order (setFillOrder) and wrapping (setWrap), so no empty cell remains where the removed *item* was. If you don't want this, rather use the raw element interface of QCPLayoutGrid.
Returns true, if successful.

See also

clearItems

17.653.4.14 selectedItems()

```
QList< QCPAbstractLegendItem * > QCPLegend::selectedItems ( ) const
```

Returns the legend items that are currently selected. If no items are selected, the list is empty.

See also

QCPAbstractLegendItem::setSelected, setSelectable

17.653.4.15 selectEvent()

```
void QCPLegend::selectEvent (
            QMouseEvent * event,
            bool additive,
            const QVariant & details,
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.653.4.16 selectionCategory()

```
QCP::Interaction QCPLegend::selectionCategory ( ) const  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.653.4.17 selectionChanged

```
void QCPLegend::selectionChanged (
            QCPLegend::SelectableParts selection )  [signal]
```

This signal is emitted when the selection state of this legend has changed.

See also

setSelectedParts, setSelectableParts

17.653.4.18 selectTest()

```
double QCPLegend::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Layout elements are sensitive to events inside their outer rect. If *pos* is within the outer rect, this method returns a value corresponding to 0.99 times the parent plot's selection tolerance. However, layout elements are not selectable by default. So if *onlySelectable* is true, -1.0 is returned.
See QCPLayerable::selectTest for a general explanation of this virtual method.
QCPLayoutElement subclasses may reimplement this method to provide more specific selection test behaviour.
Reimplemented from QCPLayoutElement.

17.653.4.19 setBorderPen()

```
void QCPLegend::setBorderPen (
            const QPen & pen )
```

Sets the pen, the border of the entire legend is drawn with.

17.653.4.20 setBrush()

```
void QCPLegend::setBrush (
            const QBrush & brush )
```

Sets the brush of the legend background.

17.653.4.21 setFont()

```
void QCPLegend::setFont (
            const QFont & font )
```

Sets the default font of legend text. Legend items that draw text (e.g. the name of a graph) will use this font by default. However, a different font can be specified on a per-item-basis by accessing the specific legend item.
This function will also set *font* on all already existing legend items.

See also

QCPAbstractLegendItem::setFont

17.653.4.22 setIconBorderPen()

```
void QCPLegend::setIconBorderPen (
            const QPen & pen )
```

Sets the pen used to draw a border around each legend icon. Legend items that draw an icon (e.g. a visual representation of the graph) will use this pen by default.
If no border is wanted, set this to *Qt::NoPen*.

17.653.4.23 setIconSize() [1/2]

```
void QCPLegend::setIconSize (
            const QSize & size )
```

Sets the size of legend icons. Legend items that draw an icon (e.g. a visual representation of the graph) will use this size by default.

17.653.4.24 setIconSize() [2/2]

```
void QCPLegend::setIconSize (
            int width,
            int height )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

17.653.4.25 setIconTextPadding()

```
void QCPLegend::setIconTextPadding (
            int padding )
```

Sets the horizontal space in pixels between the legend icon and the text next to it. Legend items that draw an icon (e.g. a visual representation of the graph) and text (e.g. the name of the graph) will use this space by default.

17.653.4.26 setSelectableParts()

```
void QCPLegend::setSelectableParts (
            const SelectableParts & selectable )
```

Sets whether the user can (de-)select the parts in *selectable* by clicking on the QCustomPlot surface. (When QCustomPlot::setInteractions contains QCP::iSelectLegend.)

However, even when *selectable* is set to a value not allowing the selection of a specific part, it is still possible to set the selection of this part manually, by calling setSelectedParts directly.

See also

SelectablePart, setSelectedParts

17.653.4.27 setSelectedBorderPen()

```
void QCPLegend::setSelectedBorderPen (
            const QPen & pen )
```

When the legend box is selected, this pen is used to draw the border instead of the normal pen set via setBorderPen.

See also

setSelectedParts, setSelectableParts, setSelectedBrush

17.653.4.28 setSelectedBrush()

```
void QCPLegend::setSelectedBrush (
            const QBrush & brush )
```

When the legend box is selected, this brush is used to draw the legend background instead of the normal brush set via setBrush.

See also

setSelectedParts, setSelectableParts, setSelectedBorderPen

17.653.4.29 setSelectedFont()

```
void QCPLegend::setSelectedFont (
            const QFont & font )
```

Sets the default font that is used by legend items when they are selected.
This function will also set *font* on all already existing legend items.

See also

setFont, QCPAbstractLegendItem::setSelectedFont

17.653.4.30 setSelectedIconBorderPen()

```
void QCPLegend::setSelectedIconBorderPen (
            const QPen & pen )
```

Sets the pen legend items will use to draw their icon borders, when they are selected.

See also

setSelectedParts, setSelectableParts, setSelectedFont

17.653.4.31 setSelectedParts()

```
void QCPLegend::setSelectedParts (
            const SelectableParts & selected )
```

Sets the selected state of the respective legend parts described by SelectablePart. When a part is selected, it uses a different pen/font and brush. If some legend items are selected and *selected* doesn't contain spItems, those items become deselected.
The entire selection mechanism is handled automatically when QCustomPlot::setInteractions contains iSelect↩ Legend. You only need to call this function when you wish to change the selection state manually.
This function can change the selection state of a part even when setSelectableParts was set to a value that actually excludes the part.
emits the selectionChanged signal when *selected* is different from the previous selection state.
Note that it doesn't make sense to set the selected state spItems here when it wasn't set before, because there's no way to specify which exact items to newly select. Do this by calling QCPAbstractLegendItem::setSelected directly on the legend item you wish to select.

See also

SelectablePart, setSelectableParts, selectTest, setSelectedBorderPen, setSelectedIconBorderPen, setSelectedBrush, setSelectedFont

17.653.4.32 setSelectedTextColor()

```
void QCPLegend::setSelectedTextColor (
            const QColor & color )
```

Sets the default text color that is used by legend items when they are selected.
This function will also set *color* on all already existing legend items.

See also

setTextColor, QCPAbstractLegendItem::setSelectedTextColor

17.653.4.33 setTextColor()

```
void QCPLegend::setTextColor (
            const QColor & color )
```

Sets the default color of legend text. Legend items that draw text (e.g. the name of a graph) will use this color by default. However, a different colors can be specified on a per-item-basis by accessing the specific legend item.
This function will also set *color* on all already existing legend items.

See also

QCPAbstractLegendItem::setTextColor

Protected Attributes

- EndingStyle **mStyle**
- double **mWidth**
- double **mLength**
- bool **mInverted**

17.654.1 Detailed Description

Handles the different ending decorations for line-like items.
For every ending a line-like item has, an instance of this class exists. For example, QCPItemLine has two endings which can be set with QCPItemLine::setHead and QCPItemLine::setTail.
The styles themselves are defined via the enum QCPLineEnding::EndingStyle. Most decorations can be modified regarding width and length, see setWidth and setLength. The direction of the ending decoration (e.g. direction an arrow is pointing) is controlled by the line-like item. For example, when both endings of a QCPItemLine are set to be arrows, they will point to opposite directions, e.g. "outward". This can be changed by setInverted, which would make the respective arrow point inward.
Note that due to the overloaded QCPLineEnding constructor, you may directly specify a QCPLineEnding::EndingStyle where actually a QCPLineEnding is expected, e.g.

17.654.2 Member Enumeration Documentation

17.654.2.1 EndingStyle

`enum QCPLineEnding::EndingStyle`
Defines the type of ending decoration for line-like items, e.g. an arrow.
The width and length of these decorations can be controlled with the functions setWidth and setLength. Some decorations like esDisc, esSquare, esDiamond and esBar only support a width, the length property is ignored.

See also

QCPItemLine::setHead, QCPItemLine::setTail, QCPItemCurve::setHead, QCPItemCurve::setTail, QCPAxis::setLowerEnding, QCPAxis::setUpperEnding

Enumerator

esNone	No ending decoration.
esFlatArrow	A filled arrow head with a straight/flat back (a triangle)
esSpikeArrow	A filled arrow head with an indented back.
esLineArrow	A non-filled arrow head with open back.
esDisc	A filled circle.
esSquare	A filled square.
esDiamond	A filled diamond (45 degrees rotated square)
esBar	A bar perpendicular to the line.
esHalfBar	A bar perpendicular to the line, pointing out to only one side (to which side can be changed with setInverted)
esSkewedBar	A bar that is skewed (skew controllable via setLength)

17.654.3 Constructor & Destructor Documentation

17.654.3.1 QCPLineEnding() [1/2]

`QCPLineEnding::QCPLineEnding ( )`
Creates a QCPLineEnding instance with default values (style esNone).

17.654.3.2 QCPLineEnding() [2/2]

```
QCPLineEnding::QCPLineEnding (
            QCPLineEnding::EndingStyle style,
            double width = 8,
            double length = 10,
            bool inverted = false )
```

Creates a QCPLineEnding instance with the specified values.

17.654.4 Member Function Documentation

17.654.4.1 realLength()

```
double QCPLineEnding::realLength ( ) const
```

Starting from the origin of this line ending (which is style specific), returns the length covered by the line ending symbol, in backward direction.
For example, the esSpikeArrow has a shorter real length than a esFlatArrow, even if both have the same setLength value, because the spike arrow has an inward curved back, which reduces the length along its center axis (the drawing origin for arrows is at the tip).
This function is used for precise, style specific placement of line endings, for example in QCPAxes.

17.654.4.2 setInverted()

```
void QCPLineEnding::setInverted (
            bool inverted )
```

Sets whether the ending decoration shall be inverted. For example, an arrow decoration will point inward when *inverted* is set to true.
Note that also the *width* direction is inverted. For symmetrical ending styles like arrows or discs, this doesn't make a difference. However, asymmetric styles like esHalfBar are affected by it, which can be used to control to which side the half bar points to.

17.654.4.3 setLength()

```
void QCPLineEnding::setLength (
            double length )
```

Sets the length of the ending decoration, if the style supports it. On arrows, for example, the length defines the size in pointing direction.

See also

setWidth

17.654.4.4 setStyle()

```
void QCPLineEnding::setStyle (
            QCPLineEnding::EndingStyle style )
```

Sets the style of the ending decoration.

17.654.4.5 setWidth()

```
void QCPLineEnding::setWidth (
            double width )
```

Sets the width of the ending decoration, if the style supports it. On arrows, for example, the width defines the size perpendicular to the arrow's pointing direction.

See also

setLength

Friends

- class **QCPLayoutElement**

17.655.1 Detailed Description

A margin group allows synchronization of margin sides if working with multiple layout elements.
QCPMarginGroup allows you to tie a margin side of two or more layout elements together, such that they will all have the same size, based on the largest required margin in the group.

In certain situations it is desirable that margins at specific sides are synchronized across layout elements. For example, if one QCPAxisRect is below another one in a grid layout, it will provide a cleaner look to the user if the left and right margins of the two axis rects are of the same size. The left axis of the top axis rect will then be at the same horizontal position as the left axis of the lower axis rect, making them appear aligned. The same applies for the right axes. This is what QCPMarginGroup makes possible.
To add/remove a specific side of a layout element to/from a margin group, use the QCPLayoutElement::setMarginGroup method. To completely break apart the margin group, either call clear, or just delete the margin group.

17.655.2 Example

First create a margin group:
Then set this group on the layout element sides:
Here, we've used the first two axis rects of the plot and synchronized their left margins with each other and their right margins with each other.

17.655.3 Constructor & Destructor Documentation

17.655.3.1 QCPMarginGroup()

```
QCPMarginGroup::QCPMarginGroup (
            QCustomPlot * parentPlot )  [explicit]
```

Creates a new QCPMarginGroup instance in *parentPlot*.

17.655.4 Member Function Documentation

17.655.4.1 clear()

```
void QCPMarginGroup::clear ( )
```

Clears this margin group. The synchronization of the margin sides that use this margin group is lifted and they will use their individual margin sizes again.

17.655.4.2 elements()

```
QList< QCPLayoutElement * > QCPMarginGroup::elements (
            QCP::MarginSide side ) const  [inline]
```

Returns a list of all layout elements that have their margin *side* associated with this margin group.

17.655.4.3 isEmpty()

```
bool QCPMarginGroup::isEmpty ( ) const
```

Returns whether this margin group is empty. If this function returns true, no layout elements use this margin group to synchronize margin sides.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.656 QCPPaintBufferPixmap Class Reference

- bool **mInvalidated**

17.656.1 Detailed Description

A paint buffer based on QPixmap, using software raster rendering.
This paint buffer is the default and fall-back paint buffer which uses software rendering and QPixmap as internal buffer. It is used if QCustomPlot::setOpenGl is false.

17.656.2 Constructor & Destructor Documentation

17.656.2.1 QCPPaintBufferPixmap()

```
QCPPaintBufferPixmap::QCPPaintBufferPixmap (
            const QSize & size,
            double devicePixelRatio )  [explicit]
```

Creates a pixmap paint buffer instancen with the specified *size* and *devicePixelRatio*, if applicable.

17.656.3 Member Function Documentation

17.656.3.1 clear()

```
void QCPPaintBufferPixmap::clear (
            const QColor & color )  [virtual]
```

Fills the entire buffer with the provided *color*. To have an empty transparent buffer, use the named color `Qt::transparent`.
This method must not be called if there is currently a painter (acquired with startPainting) active.
Implements QCPAbstractPaintBuffer.

17.656.3.2 draw()

```
void QCPPaintBufferPixmap::draw (
            QCPPainter * painter ) const  [virtual]
```

Draws the contents of this buffer with the provided *painter*. This is the method that is used to finally join all paint buffers and draw them onto the screen.
Implements QCPAbstractPaintBuffer.

17.656.3.3 reallocateBuffer()

```
void QCPPaintBufferPixmap::reallocateBuffer ( )  [protected], [virtual]
```

Reallocates the internal buffer with the currently configured size (setSize) and device pixel ratio, if applicable (setDevicePixelRatio). It is called as soon as any of those properties are changed on this paint buffer.

Note

Subclasses of QCPAbstractPaintBuffer must call their reimplementation of this method in their constructor, to perform the first allocation (this can not be done by the base class because calling pure virtual methods in base class constructors is not possible).

Implements QCPAbstractPaintBuffer.

17.656.3.4 startPainting()

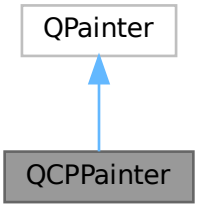
```
QCPPainter * QCPPaintBufferPixmap::startPainting ( )  [virtual]
```

Returns a QCPPainter which is ready to draw to this buffer. The ownership and thus the responsibility to delete the painter after the painting operations are complete is given to the caller of this method.
Once you are done using the painter, delete the painter and call donePainting.
While a painter generated with this method is active, you must not call setSize, setDevicePixelRatio or clear.
This method may return 0, if a painter couldn't be activated on the buffer. This usually indicates a problem with the respective painting backend.
Implements QCPAbstractPaintBuffer.
The documentation for this class was generated from the following files:

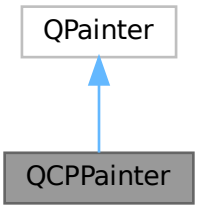
- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.657 QCPPainter Class Reference

QPainter subclass used internally.
Inheritance diagram for QCPPainter:



Collaboration diagram for QCPPainter:



Public Types

- enum PainterMode { pmDefault = 0x00 , pmVectorized = 0x01 , pmNoCaching = 0x02 , pmNonCosmetic = 0x04 }

- void setPen (const QColor &color)
- void setPen (Qt::PenStyle penStyle)
- void drawLine (const QLineF &line)
- void **drawLine** (const QPointF &p1, const QPointF &p2)
- void save ()
- void restore ()
- void makeNonCosmetic ()

Protected Attributes

- PainterModes **mModes**
- bool **mIsAntialiasing**
- QStack< bool > **mAntialiasingStack**

17.657.1 Detailed Description

QPainter subclass used internally.
This QPainter subclass is used to provide some extended functionality e.g. for tweaking position consistency between antialiased and non-antialiased painting. Further it provides workarounds for QPainter quirks.

Warning

> This class intentionally hides non-virtual functions of QPainter, e.g. setPen, save and restore. So while it is possible to pass a QCPPainter instance to a function that expects a QPainter pointer, some of the workarounds and tweaks will be unavailable to the function (because it will call the base class implementations of the functions actually hidden by QCPPainter).

17.657.2 Member Enumeration Documentation

17.657.2.1 PainterMode

enum QCPPainter::PainterMode

Defines special modes the painter can operate in. They disable or enable certain subsets of features/fixes/workarounds, depending on whether they are wanted on the respective output device.

Enumerator

pmDefault	0x00 Default mode for painting on screen devices
pmVectorized	0x01 Mode for vectorized painting (e.g. PDF export). For example, this prevents some antialiasing fixes.
pmNoCaching	0x02 Mode for all sorts of exports (e.g. PNG, PDF,...). For example, this prevents using cached pixmap labels
pmNonCosmetic	0x04 Turns pen widths 0 to 1, i.e. disables cosmetic pens. (A cosmetic pen is always drawn with width 1 pixel in the vector image/pdf viewer, independent of zoom.)

17.657.3 Constructor & Destructor Documentation

17.657.3.1 QCPPainter() [1/2]

```
QCPPainter::QCPPainter ( )
```

Creates a new QCPPainter instance and sets default values

17.657.3.2 QCPPainter() [2/2]

```
QCPPainter::QCPPainter (
            QPaintDevice * device )  [explicit]
```

Creates a new QCPPainter instance on the specified paint *device* and sets default values. Just like the analogous QPainter constructor, begins painting on *device* immediately.
Like begin, this method sets QPainter::NonCosmeticDefaultPen in Qt versions before Qt5.

17.657.4 Member Function Documentation

17.657.4.1 begin()

```
bool QCPPainter::begin (
            QPaintDevice * device )
```

Sets the QPainter::NonCosmeticDefaultPen in Qt versions before Qt5 after beginning painting on *device*. This is necessary to get cosmetic pen consistency across Qt versions, because since Qt5, all pens are non-cosmetic by default, and in Qt4 this render hint must be set to get that behaviour.
The Constructor QCPPainter(QPaintDevice *device) which directly starts painting also sets the render hint as appropriate.

Note

this function hides the non-virtual base class implementation.

17.657.4.2 drawLine()

```
void QCPPainter::drawLine (
            const QLineF & line )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Works around a Qt bug introduced with Qt 4.8 which makes drawing QLineF unpredictable when antialiasing is disabled. Thus when antialiasing is disabled, it rounds the *line* to integer coordinates and then passes it to the original drawLine.

Note

this function hides the non-virtual base class implementation.

17.657.4.3 makeNonCosmetic()

```
void QCPPainter::makeNonCosmetic ( )
```

Changes the pen width to 1 if it currently is 0. This function is called in the setPen overrides when the pmNonCosmetic mode is set.

17.657.4.4 restore()

```
void QCPPainter::restore ( )
```

Restores the painter (see QPainter::restore). Since QCPPainter adds some new internal state to QPainter, the save/restore functions are reimplemented to also save/restore those members.

Note

this function hides the non-virtual base class implementation.

See also

save

17.657.4.5 save()

```
void QCPPainter::save ( )
```

Saves the painter (see QPainter::save). Since QCPPainter adds some new internal state to QPainter, the save/restore functions are reimplemented to also save/restore those members.

Note

this function hides the non-virtual base class implementation.

See also

restore

17.657.4.6 setAntialiasing()

```
void QCPPainter::setAntialiasing (
            bool enabled )
```

Sets whether painting uses antialiasing or not. Use this method instead of using setRenderHint with QPainter↩ ::Antialiasing directly, as it allows QCPPainter to regain pixel exactness between antialiased and non-antialiased painting (Since Qt $<$ 5.0 uses slightly different coordinate systems for AA/Non-AA painting).

17.657.4.7 setMode()

```
void QCPPainter::setMode (
            QCPPainter::PainterMode mode,
            bool enabled = true )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the mode of the painter. This controls whether the painter shall adjust its fixes/workarounds optimized for certain output devices.

17.657.4.8 setModes()

```
void QCPPainter::setModes (
            PainterModes modes )
```

Sets the mode of the painter. This controls whether the painter shall adjust its fixes/workarounds optimized for certain output devices.

17.657.4.9 setPen() [1/3]

```
void QCPPainter::setPen (
            const QColor & color )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the pen (by color) of the painter and applies certain fixes to it, depending on the mode of this QCPPainter.

Note

this function hides the non-virtual base class implementation.

17.657.4.10 setPen() [2/3]

```
void QCPPainter::setPen (
            const QPen & pen )
```

Sets the pen of the painter and applies certain fixes to it, depending on the mode of this QCPPainter.

Note

this function hides the non-virtual base class implementation.

17.657.4.11 setPen() [3/3]

```
void QCPPainter::setPen (
            Qt::PenStyle penStyle )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the pen (by style) of the painter and applies certain fixes to it, depending on the mode of this QCPPainter.

Note

this function hides the non-virtual base class implementation.

The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h

- virtual int findBegin (double sortKey, bool expandedRange=true) const =0
- virtual int findEnd (double sortKey, bool expandedRange=true) const =0

17.658.1 Detailed Description

Defines an abstract interface for one-dimensional plottables.
This class contains only pure virtual methods which define a common interface to the data of one-dimensional plottables.
For example, it is implemented by the template class QCPAbstractPlottable1D (the preferred base class for one-dimensional plottables). So if you use that template class as base class of your one-dimensional plottable, you won't have to care about implementing the 1d interface yourself.
If your plottable doesn't derive from QCPAbstractPlottable1D but still wants to provide a 1d interface (e.g. like QCPErrorBars does), you should inherit from both QCPAbstractPlottable and QCPPlottableInterface1D and accordingly reimplement the pure virtual methods of the 1d interface, matching your data container. Also, reimplement QCPAbstractPlottable::interface1D to return the `this` pointer.
If you have a QCPAbstractPlottable pointer, you can check whether it implements this interface by calling QCPAbstractPlottable::interface1D and testing it for a non-zero return value. If it indeed implements this interface, you may use it to access the plottable's data without needing to know the exact type of the plottable or its data point type.

17.658.2 Member Function Documentation

17.658.2.1 dataCount()

```
int QCPPlottableInterface1D::dataCount ( ) const  [pure virtual]
```

Returns the number of data points of the plottable.

Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat and QCPErrorBars.

17.658.2.2 dataMainKey()

```
double QCPPlottableInterface1D::dataMainKey (
            int index ) const  [pure virtual]
```

Returns the main key of the data point at the given *index*.

What the main key is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.

Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat and QCPErrorBars.

17.658.2.3 dataMainValue()

```
double QCPPlottableInterface1D::dataMainValue (
            int index ) const  [pure virtual]
```

Returns the main value of the data point at the given *index*.

What the main value is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.

Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat and QCPErrorBars.

17.658.2.4 dataPixelPosition()

```
QPointF QCPPlottableInterface1D::dataPixelPosition (
            int index ) const  [pure virtual]
```

Returns the pixel position on the widget surface at which the data point at the given *index* appears.

Usually this corresponds to the point of dataMainKey/ dataMainValue, in pixel coordinates. However, depending on the plottable, this might be a different apparent position than just a coord-to-pixel transform of those values. For example, QCPBars apparent data values can be shifted depending on their stacking, bar grouping or configured base value.

Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat QCPBars, and QCPErrorBars.

17.658.2.5 dataSortKey()

```
double QCPPlottableInterface1D::dataSortKey (
            int index ) const  [pure virtual]
```

Returns the sort key of the data point at the given *index*.

What the sort key is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.

Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat and QCPErrorBars.

17.658.2.6 dataValueRange()

```
QCPRange QCPPlottableInterface1D::dataValueRange (
            int index ) const  [pure virtual]
```

Returns the value range of the data point at the given *index*.
What the value range is, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat and QCPErrorBars.

17.658.2.7 findBegin()

```
int QCPPlottableInterface1D::findBegin (
            double sortKey,
            bool expandedRange = true ) const  [pure virtual]
```

Returns the index of the data point with a (sort-)key that is equal to, just below, or just above *sortKey*. If *expanded↩ Range* is true, the data point just below *sortKey* will be considered, otherwise the one just above.
This can be used in conjunction with findEnd to iterate over data points within a given key range, including or excluding the bounding data points that are just beyond the specified range.
If *expandedRange* is true but there are no data points below *sortKey*, 0 is returned.
If the container is empty, returns 0 (in that case, findEnd will also return 0, so a loop using these methods will not iterate over the index 0).

See also

findEnd, QCPDataContainer::findBegin

Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat and QCPErrorBars.

17.658.2.8 findEnd()

```
int QCPPlottableInterface1D::findEnd (
            double sortKey,
            bool expandedRange = true ) const  [pure virtual]
```

Returns the index one after the data point with a (sort-)key that is equal to, just above, or just below *sortKey*. If *expandedRange* is true, the data point just above *sortKey* will be considered, otherwise the one just below.
This can be used in conjunction with findBegin to iterate over data points within a given key range, including the bounding data points that are just below and above the specified range.
If *expandedRange* is true but there are no data points above *sortKey*, the index just above the highest data point is returned.
If the container is empty, returns 0.

See also

findBegin, QCPDataContainer::findEnd

Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat and QCPErrorBars.

17.658.2.9 selectTestRect()

```
QCPDataSelection QCPPlottableInterface1D::selectTestRect (
            const QRectF & rect,
            bool onlySelectable ) const  [pure virtual]
```

Returns a data selection containing all the data points of this plottable which are contained (or hit by) *rect*. This is used mainly in the selection rect interaction for data selection (data selection mechanism).
If *onlySelectable* is true, an empty QCPDataSelection is returned if this plottable is not selectable (i.e. if QCPAbstractPlottable::setSelectable is QCP::stNone).

Note

rect must be a normalized rect (positive or zero width and height). This is especially important when using the rect of QCPSelectionRect::accepted, which is not necessarily normalized. Use `QRect::normalized()` when passing a rect which might not be normalized.

Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP
QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat
QCPBars, QCPStatisticalBox, QCPFinancial, and QCPErrorBars.

17.658.2.10 sortKeyIsMainKey()

```
bool QCPPlottableInterface1D::sortKeyIsMainKey ( ) const  [pure virtual]
```

Returns whether the sort key (dataSortKey) is identical to the main key (dataMainKey).
What the sort and main keys are, is defined by the plottable's data type. See the QCPDataContainer DataType documentation for details about this naming convention.
Implemented in QCPAbstractPlottable1D< DataType >, QCPAbstractPlottable1D< QCPBarsData >, QCPAbstractPlottable1D< QCP
QCPAbstractPlottable1D< QCPFinancialData >, QCPAbstractPlottable1D< QCPGraphData >, QCPAbstractPlottable1D< QCPStat
and QCPErrorBars.

17.659.1 Detailed Description

A legend item representing a plottable with an icon and the plottable name.
This is the standard legend item for plottables. It displays an icon of the plottable next to the plottable name. The icon is drawn by the respective plottable itself (QCPAbstractPlottable::drawLegendIcon), and tries to give an intuitive symbol for the plottable. For example, the QCPGraph draws a centered horizontal line and/or a single scatter point in the middle.
Legend items of this type are always associated with one plottable (retrievable via the plottable() function and settable with the constructor). You may change the font of the plottable name with setFont. Icon padding and border pen is taken from the parent QCPLegend, see QCPLegend::setIconBorderPen and QCPLegend::setIconTextPadding.
The function QCPAbstractPlottable::addToLegend/ QCPAbstractPlottable::removeFromLegend creates/removes legend items of this type.
Since QCPLegend is based on QCPLayoutGrid, a legend item itself is just a subclass of QCPLayoutElement. While it could be added to a legend (or any other layout) via the normal layout interface, QCPLegend has specialized functions for handling legend items conveniently, see the documentation of QCPLegend.

17.659.2 Constructor & Destructor Documentation

17.659.2.1 QCPPlottableLegendItem()

```
QCPPlottableLegendItem::QCPPlottableLegendItem (
            QCPLegend * parent,
            QCPAbstractPlottable * plottable )
```

Creates a new legend item associated with *plottable*.
Once it's created, it can be added to the legend via QCPLegend::addItem.
A more convenient way of adding/removing a plottable to/from the legend is via the functions QCPAbstractPlottable::addToLegend and QCPAbstractPlottable::removeFromLegend.

17.659.3 Member Function Documentation

17.659.3.1 draw()

```
void QCPPlottableLegendItem::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractLegendItem.

17.659.3.2 minimumOuterSizeHint()

```
QSize QCPPlottableLegendItem::minimumOuterSizeHint ( ) const  [protected], [virtual]
```

Returns the suggested minimum size this layout element (the outerRect) may be compressed to, if no manual minimum size is set.
if a minimum size (setMinimumSize) was not set manually, parent layouts use the returned size (usually indirectly through QCPLayout::getFinalMinimumOuterSize) to determine the minimum allowed size of this layout element.
A manual minimum size is considered set if it is non-zero.
The default implementation simply returns the sum of the horizontal margins for the width and the sum of the vertical margins for the height. Reimplementations may use their detailed knowledge about the layout element's content to provide size hints.
Reimplemented from QCPLayoutElement.

17.660.1 Detailed Description

The main container for polar plots, representing the angular axis as a circle.

Warning

> In this QCustomPlot version, polar plots are a tech preview. Expect documentation and functionality to be incomplete, as well as changing public interfaces in the future.

17.660.2 Member Enumeration Documentation

17.660.2.1 LabelMode

enum QCPPolarAxisAngular::LabelMode
TODO

17.660.2.2 SelectablePart

enum QCPPolarAxisAngular::SelectablePart
Defines the selectable parts of an axis.

See also

setSelectableParts, setSelectedParts

Enumerator

spNone	None of the selectable parts.
spAxis	The axis backbone and tick marks.
spTickLabels	Tick labels (numbers) of this axis (as a whole, not individually)
spAxisLabel	The axis label.

17.660.3 Constructor & Destructor Documentation

17.660.3.1 QCPPolarAxisAngular()

```
QCPPolarAxisAngular::QCPPolarAxisAngular (
            QCustomPlot * parentPlot )  [explicit]
```
Creates a QCPPolarAxis instance and sets default values. An axis is added for each of the four sides, the top and right axes are set invisible initially.

17.660.4 Member Function Documentation

17.660.4.1 addRadialAxis()

```
QCPPolarAxisRadial * QCPPolarAxisAngular::addRadialAxis (
            QCPPolarAxisRadial * axis = 0 )
```
Adds a new axis to the axis rect side specified with *type*, and returns it. If *axis* is 0, a new QCPAxis instance is created internally. QCustomPlot owns the returned axis, so if you want to remove an axis, use removeAxis instead of deleting it manually.
You may inject QCPAxis instances (or subclasses of QCPAxis) by setting *axis* to an axis that was previously created outside QCustomPlot. It is important to note that QCustomPlot takes ownership of the axis, so you may not delete it afterwards. Further, the *axis* must have been created with this axis rect as parent and with the same axis type as specified in *type*. If this is not the case, a debug output is generated, the axis is not added, and the method returns 0.
This method can not be used to move *axis* between axis rects. The same *axis* instance must not be added multiple times to the same or different axis rects.
If an axis rect side already contains one or more axes, the lower and upper endings of the new axis (QCPAxis::setLowerEnding, QCPAxis::setUpperEnding) are set to QCPLineEnding::esHalfBar.

See also

addAxes, setupFullAxesBox

17.660.4.2 applyDefaultAntialiasingHint()

```
void QCPPolarAxisAngular::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```
Reimplemented from QCPLayoutElement.

17.660.4.3 bottom()

```
int QCPPolarAxisAngular::bottom ( ) const  [inline]
```
Returns the pixel position of the bottom border of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.4 bottomLeft()

```
QPoint QCPPolarAxisAngular::bottomLeft ( ) const  [inline]
```
Returns the bottom left corner of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.5 bottomRight()

```
QPoint QCPPolarAxisAngular::bottomRight ( ) const  [inline]
```
Returns the bottom right corner of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.6 center()

```
QPoint QCPPolarAxisAngular::center ( ) const  [inline]
```
Returns the center of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.7 coordToPixel()

```
QPointF QCPPolarAxisAngular::coordToPixel (
            double angleCoord,
            double radiusCoord ) const
```
Transforms *value*, in coordinates of the axis, to pixel coordinates of the QCustomPlot widget.

17.660.4.8 draw()

```
void QCPPolarAxisAngular::draw (
            QCPPainter * painter )  [protected], [virtual]
```
Reimplemented from QCPLayoutElement.

17.660.4.9 elements()

```
QList< QCPLayoutElement * > QCPPolarAxisAngular::elements (
            bool recursive ) const  [virtual]
```
Returns a list of all child elements in this layout element. If *recursive* is true, all sub-child elements are included in the list, too.

Warning

> There may be `nullptr` entries in the returned list. For example, QCPLayoutGrid may have empty cells which yield `nullptr` at the respective index.

Reimplemented from QCPLayoutElement.

17.660.4.10 getPartAt()

```
QCPPolarAxisAngular::SelectablePart QCPPolarAxisAngular::getPartAt (
            const QPointF & pos ) const
```
Returns the part of the axis that is hit by *pos* (in pixels). The return value of this function is independent of the user-selectable parts defined with setSelectableParts. Further, this function does not change the current selection state of the axis.
If the axis is not visible (setVisible), this function always returns spNone.

See also

setSelectedParts, setSelectableParts, QCustomPlot::setInteractions

17.660.4.11 height()

```
int QCPPolarAxisAngular::height ( ) const  [inline]
```

Returns the pixel height of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.12 insetLayout()

```
QCPLayoutInset * QCPPolarAxisAngular::insetLayout ( ) const  [inline]
```

Returns the inset layout of this axis rect. It can be used to place other layout elements (or even layouts with multiple other elements) inside/on top of an axis rect.

See also

QCPLayoutInset

17.660.4.13 left()

```
int QCPPolarAxisAngular::left ( ) const  [inline]
```

Returns the pixel position of the left border of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.14 mouseMoveEvent()

```
void QCPPolarAxisAngular::mouseMoveEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user moves the mouse while holding a mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.660.4.15 mousePressEvent()

```
void QCPPolarAxisAngular::mousePressEvent (
            QMouseEvent * event,
            const QVariant & details )  [protected], [virtual]
```

This event gets called when the user presses a mouse button while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *details* contains layerable-specific details about the hit, which were generated in the previous call to selectTest. For example, One-dimensional plottables like QCPGraph or QCPBars convey the clicked data point in the *details* parameter, as QCPDataSelection packed as QVariant. Multi-part objects convey the specific `SelectablePart` that was hit (e.g. QCPAxis::SelectablePart in the case of axes).
QCustomPlot uses an event propagation system that works the same as Qt's system. If your layerable doesn't reimplement the mousePressEvent or explicitly calls `event->ignore()` in its reimplementation, the event will be propagated to the next layerable in the stacking order.
Once a layerable has accepted the mousePressEvent, it is considered the mouse grabber and will receive all following calls to mouseMoveEvent or mouseReleaseEvent for this mouse interaction (a "mouse interaction" in this context ends with the release).
The default implementation does nothing except explicitly ignoring the event with `event->ignore()`.

See also

mouseMoveEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.660.4.16 mouseReleaseEvent()

```
void QCPPolarAxisAngular::mouseReleaseEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user releases the mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseMoveEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.660.4.17 moveRange()

```
void QCPPolarAxisAngular::moveRange (
            double diff )
```

If the scale type (setScaleType) is stLinear, *diff* is added to the lower and upper bounds of the range. The range is simply moved by *diff*.
If the scale type is stLogarithmic, the range bounds are multiplied by *diff*. This corresponds to an apparent "linear" move in logarithmic scaling by a distance of log(diff).

17.660.4.18 pixelToCoord()

```
void QCPPolarAxisAngular::pixelToCoord (
            QPointF pixelPos,
            double & angleCoord,
            double & radiusCoord ) const
```

Transforms *value*, in pixel coordinates of the QCustomPlot widget, to axis coordinates.

17.660.4.19 radialAxes()

```
QList< QCPPolarAxisRadial * > QCPPolarAxisAngular::radialAxes ( ) const
```

Returns all axes on the axis rect sides specified with *types*.
types may be a single QCPAxis::AxisType or an `or`-combination, to get the axes of multiple sides.

See also

axis

17.660.4.20 radialAxis()

```
QCPPolarAxisRadial * QCPPolarAxisAngular::radialAxis (
            int index = 0 ) const
```

Returns the axis with the given *index* on the axis rect side specified with *type*.

See also

axisCount, axes

17.660.4.21 radialAxisCount()

```
int QCPPolarAxisAngular::radialAxisCount ( ) const
```

Returns the number of axes on the axis rect side specified with *type*.

See also

axis

17.660.4.22 removeRadialAxis()

```
bool QCPPolarAxisAngular::removeRadialAxis (
            QCPPolarAxisRadial * radialAxis )
```

Removes the specified *axis* from the axis rect and deletes it.
Returns true on success, i.e. if *axis* was a valid axis in this axis rect.

See also

addAxis

17.660.4.23 rescale()

```
void QCPPolarAxisAngular::rescale (
            bool onlyVisiblePlottables = false )
```

Changes the axis range such that all plottables associated with this axis are fully visible in that dimension.

See also

QCPAbstractPlottable::rescaleAxes, QCustomPlot::rescaleAxes

17.660.4.24 right()

```
int QCPPolarAxisAngular::right ( ) const  [inline]
```

Returns the pixel position of the right border of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.25 scaleRange() [1/2]

```
void QCPPolarAxisAngular::scaleRange (
            double factor )
```

Scales the range of this axis by *factor* around the center of the current axis range. For example, if *factor* is 2.0, then the axis range will double its size, and the point at the axis range center won't have changed its position in the QCustomPlot widget (i.e. coordinates around the center will have moved symmetrically closer).
If you wish to scale around a different coordinate than the current axis range center, use the overload scaleRange(double factor, double center).

17.660.4.26 scaleRange() [2/2]

```
void QCPPolarAxisAngular::scaleRange (
            double factor,
            double center )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Scales the range of this axis by *factor* around the coordinate *center*. For example, if *factor* is 2.0, *center* is 1.0, then the axis range will double its size, and the point at coordinate 1.0 won't have changed its position in the QCustomPlot widget (i.e. coordinates around 1.0 will have moved symmetrically closer to 1.0).

See also

scaleRange(double factor)

17.660.4.27 selectionCategory()

```
QCP::Interaction QCPPolarAxisAngular::selectionCategory ( ) const  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.660.4.28 selectTest()

```
double QCPPolarAxisAngular::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = 0 ) const  [virtual]
```

Layout elements are sensitive to events inside their outer rect. If *pos* is within the outer rect, this method returns a value corresponding to 0.99 times the parent plot's selection tolerance. However, layout elements are not selectable by default. So if *onlySelectable* is true, -1.0 is returned.
See QCPLayerable::selectTest for a general explanation of this virtual method.
QCPLayoutElement subclasses may reimplement this method to provide more specific selection test behaviour.
Reimplemented from QCPLayoutElement.

17.660.4.29 setBackground() [1/3]

```
void QCPPolarAxisAngular::setBackground (
            const QBrush & brush )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets *brush* as the background brush. The axis rect background will be filled with this brush. Since axis rects place themselves on the "background" layer by default, the axis rect backgrounds are usually drawn below everything else.
The brush will be drawn before (under) any background pixmap, which may be specified with setBackground(const QPixmap &pm).
To disable drawing of a background brush, set *brush* to Qt::NoBrush.

See also

setBackground(const QPixmap &pm)

17.660.4.30 setBackground() [2/3]

```
void QCPPolarAxisAngular::setBackground (
            const QPixmap & pm )
```

Sets *pm* as the axis background pixmap. The axis background pixmap will be drawn inside the axis rect. Since axis rects place themselves on the "background" layer by default, the axis rect backgrounds are usually drawn below everything else.
For cases where the provided pixmap doesn't have the same size as the axis rect, scaling can be enabled with setBackgroundScaled and the scaling mode (i.e. whether and how the aspect ratio is preserved) can be set with setBackgroundScaledMode. To set all these options in one call, consider using the overloaded version of this function.
Below the pixmap, the axis rect may be optionally filled with a brush, if specified with setBackground(const QBrush &brush).

See also

setBackgroundScaled, setBackgroundScaledMode, setBackground(const QBrush &brush)

17.660.4.31 setBackground() [3/3]

```
void QCPPolarAxisAngular::setBackground (
            const QPixmap & pm,
            bool scaled,
            Qt::AspectRatioMode mode = Qt::KeepAspectRatioByExpanding )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Allows setting the background pixmap of the axis rect, whether it shall be scaled and how it shall be scaled in one call.

See also

setBackground(const QPixmap &pm), setBackgroundScaled, setBackgroundScaledMode

17.660.4.32 setBackgroundScaled()

```
void QCPPolarAxisAngular::setBackgroundScaled (
            bool scaled )
```

Sets whether the axis background pixmap shall be scaled to fit the axis rect or not. If *scaled* is set to true, you may control whether and how the aspect ratio of the original pixmap is preserved with setBackgroundScaledMode.
Note that the scaled version of the original pixmap is buffered, so there is no performance penalty on replots. (Except when the axis rect dimensions are changed continuously.)

See also

setBackground, setBackgroundScaledMode

17.660.4.33 setBackgroundScaledMode()

```
void QCPPolarAxisAngular::setBackgroundScaledMode (
            Qt::AspectRatioMode mode )
```

If scaling of the axis background pixmap is enabled (setBackgroundScaled), use this function to define whether and how the aspect ratio of the original pixmap passed to setBackground is preserved.

See also

setBackground, setBackgroundScaled

17.660.4.34 setBasePen()

```
void QCPPolarAxisAngular::setBasePen (
            const QPen & pen )
```

Sets the pen, the axis base line is drawn with.

See also

setTickPen, setSubTickPen

17.660.4.35 setLabel()

```
void QCPPolarAxisAngular::setLabel (
            const QString & str )
```

Sets the text of the axis label that will be shown below/above or next to the axis, depending on its orientation. To disable axis labels, pass an empty string as *str*.

17.660.4.36 setLabelColor()

```
void QCPPolarAxisAngular::setLabelColor (
            const QColor & color )
```

Sets the color of the axis label.

See also

setLabelFont

17.660.4.37 setLabelFont()

```
void QCPPolarAxisAngular::setLabelFont (
            const QFont & font )
```

Sets the font of the axis label.

See also

setLabelColor

17.660.4.38 setLabelPadding()

```
void QCPPolarAxisAngular::setLabelPadding (
            int padding )
```

Sets the distance between the tick labels and the axis label.

See also

setTickLabelPadding, setPadding

17.660.4.39 setNumberFormat()

```
void QCPPolarAxisAngular::setNumberFormat (
            const QString & formatCode )
```

Sets the number format for the numbers in tick labels. This *formatCode* is an extended version of the format code used e.g. by QString::number() and QLocale::toString(). For reference about that, see the "Argument Formats" section in the detailed description of the QString class.
formatCode is a string of one, two or three characters. The first character is identical to the normal format code used by Qt. In short, this means: 'e'/'E' scientific format, 'f' fixed format, 'g'/'G' scientific or fixed, whichever is shorter.
The second and third characters are optional and specific to QCustomPlot:
If the first char was 'e' or 'g', numbers are/might be displayed in the scientific format, e.g. "5.5e9", which might be visually unappealing in a plot. So when the second char of *formatCode* is set to 'b' (for "beautiful"), those exponential numbers are formatted in a more natural way, i.e. "5.5 [multiplication sign] 10 [superscript] 9". By default, the multiplication sign is a centered dot. If instead a cross should be shown (as is usual in the USA), the third char of *formatCode* can be set to 'c'. The inserted multiplication signs are the UTF-8 characters 215 (0xD7) for the cross and 183 (0xB7) for the dot.
Examples for *formatCode:*

- `g` normal format code behaviour. If number is small, fixed format is used, if number is large, normal scientific format is used
- `gb` If number is small, fixed format is used, if number is large, scientific format is used with beautifully typeset decimal powers and a dot as multiplication sign
- `ebc` All numbers are in scientific format with beautifully typeset decimal power and a cross as multiplication sign
- `fb` illegal format code, since fixed format doesn't support (or need) beautifully typeset decimal powers. Format code will be reduced to 'f'.
- `hello` illegal format code, since first char is not 'e', 'E', 'f', 'g' or 'G'. Current format code will not be changed.

17.660.4.40 setNumberPrecision()

```
void QCPPolarAxisAngular::setNumberPrecision (
            int precision )
```

Sets the precision of the tick label numbers. See QLocale::toString(double i, char f, int prec) for details. The effect of precisions are most notably for number Formats starting with 'e', see setNumberFormat

17.660.4.41 setRange() [1/3]

```
void QCPPolarAxisAngular::setRange (
            const QCPRange & range )
```

Sets the range of the axis.
This slot may be connected with the rangeChanged signal of another axis so this axis is always synchronized with the other axis range, when it changes.
To invert the direction of an axis, use setRangeReversed.

17.660.4.42 setRange() [2/3]

```
void QCPPolarAxisAngular::setRange (
            double lower,
            double upper )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the lower and upper bound of the axis range.
To invert the direction of an axis, use setRangeReversed.
There is also a slot to set a range, see setRange(const QCPRange &range).

17.660.4.43 setRange() [3/3]

```
void QCPPolarAxisAngular::setRange (
            double position,
            double size,
            Qt::AlignmentFlag alignment )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the range of the axis.
The *position* coordinate indicates together with the *alignment* parameter, where the new range will be positioned. *size* defines the size of the new axis range. *alignment* may be Qt::AlignLeft, Qt::AlignRight or Qt::AlignCenter. This will cause the left border, right border, or center of the range to be aligned with *position*. Any other values of *alignment* will default to Qt::AlignCenter.

17.660.4.44 setRangeLower()

```
void QCPPolarAxisAngular::setRangeLower (
            double lower )
```

Sets the lower bound of the axis range. The upper bound is not changed.

See also

setRange

17.660.4.45 setRangeReversed()

```
void QCPPolarAxisAngular::setRangeReversed (
            bool reversed )
```

Sets whether the axis range (direction) is displayed reversed. Normally, the values on horizontal axes increase left to right, on vertical axes bottom to top. When *reversed* is set to true, the direction of increasing values is inverted.
Note that the range and data interface stays the same for reversed axes, e.g. the *lower* part of the setRange interface will still reference the mathematically smaller number than the *upper* part.

17.660.4.46 setRangeUpper()

```
void QCPPolarAxisAngular::setRangeUpper (
            double upper )
```

Sets the upper bound of the axis range. The lower bound is not changed.

See also

setRange

17.660.4.47 setSelectableParts()

```
void QCPPolarAxisAngular::setSelectableParts (
            const QCPPolarAxisAngular::SelectableParts & selectableParts )
```

Sets whether the user can (de-)select the parts in *selectable* by clicking on the QCustomPlot surface. (When QCustomPlot::setInteractions contains iSelectAxes.)
However, even when *selectable* is set to a value not allowing the selection of a specific part, it is still possible to set the selection of this part manually, by calling setSelectedParts directly.

See also

SelectablePart, setSelectedParts

17.660.4.48 setSelectedBasePen()

```
void QCPPolarAxisAngular::setSelectedBasePen (
            const QPen & pen )
```

Sets the pen that is used to draw the axis base line when selected.

See also

setBasePen, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.660.4.49 setSelectedLabelColor()

```
void QCPPolarAxisAngular::setSelectedLabelColor (
            const QColor & color )
```

Sets the color that is used for the axis label when it is selected.

See also

setLabelColor, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.660.4.50 setSelectedLabelFont()

```
void QCPPolarAxisAngular::setSelectedLabelFont (
            const QFont & font )
```

Sets the font that is used for the axis label when it is selected.

See also

setLabelFont, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.660.4.51 setSelectedParts()

```
void QCPPolarAxisAngular::setSelectedParts (
            const QCPPolarAxisAngular::SelectableParts & selectedParts )
```

Sets the selected state of the respective axis parts described by SelectablePart. When a part is selected, it uses a different pen/font.
The entire selection mechanism for axes is handled automatically when QCustomPlot::setInteractions contains iSelectAxes. You only need to call this function when you wish to change the selection state manually.
This function can change the selection state of a part, independent of the setSelectableParts setting.
emits the selectionChanged signal when *selected* is different from the previous selection state.

See also

SelectablePart, setSelectableParts, selectTest, setSelectedBasePen, setSelectedTickPen, setSelectedSubTickPen, setSelectedTickLabelFont, setSelectedLabelFont, setSelectedTickLabelColor, setSelectedLabelColor

17.660.4.52 setSelectedSubTickPen()

```
void QCPPolarAxisAngular::setSelectedSubTickPen (
            const QPen & pen )
```

Sets the pen that is used to draw the subticks when selected.

See also

setSubTickPen, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.660.4.53 setSelectedTickLabelColor()

```
void QCPPolarAxisAngular::setSelectedTickLabelColor (
            const QColor & color )
```

Sets the color that is used for tick labels when they are selected.

See also

setTickLabelColor, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.660.4.54 setSelectedTickLabelFont()

```
void QCPPolarAxisAngular::setSelectedTickLabelFont (
            const QFont & font )
```

Sets the font that is used for tick labels when they are selected.

See also

setTickLabelFont, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.660.4.55 setSelectedTickPen()

```
void QCPPolarAxisAngular::setSelectedTickPen (
            const QPen & pen )
```

Sets the pen that is used to draw the (major) ticks when selected.

See also

setTickPen, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.660.4.56 setSubTickLength()

```
void QCPPolarAxisAngular::setSubTickLength (
            int inside,
            int outside = 0 )
```

Sets the length of the subticks in pixels. *inside* is the length the subticks will reach inside the plot and *outside* is the length they will reach outside the plot. If *outside* is greater than zero, the tick labels and axis label will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setTickLength, setSubTickLengthIn, setSubTickLengthOut

17.660.4.57 setSubTickLengthIn()

```
void QCPPolarAxisAngular::setSubTickLengthIn (
            int inside )
```

Sets the length of the inward subticks in pixels. *inside* is the length the subticks will reach inside the plot.

See also

setSubTickLengthOut, setSubTickLength, setTickLength

17.660.4.58 setSubTickLengthOut()

```
void QCPPolarAxisAngular::setSubTickLengthOut (
            int outside )
```

Sets the length of the outward subticks in pixels. *outside* is the length the subticks will reach outside the plot. If *outside* is greater than zero, the tick labels will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setSubTickLengthIn, setSubTickLength, setTickLength

17.660.4.59 setSubTickPen()

```
void QCPPolarAxisAngular::setSubTickPen (
            const QPen & pen )
```

Sets the pen, subtick marks will be drawn with.

See also

setSubTickCount, setSubTickLength, setBasePen

17.660.4.60 setSubTicks()

```
void QCPPolarAxisAngular::setSubTicks (
            bool show )
```

Sets whether sub tick marks are displayed.
Sub ticks are only potentially visible if (major) ticks are also visible (see setTicks)

See also

setTicks

17.660.4.61 setTicker()

```
void QCPPolarAxisAngular::setTicker (
            QSharedPointer< QCPAxisTicker > ticker )
```

The axis ticker is responsible for generating the tick positions and tick labels. See the documentation of QCPAxisTicker for details on how to work with axis tickers.
You can change the tick positioning/labeling behaviour of this axis by setting a different QCPAxisTicker subclass using this method. If you only wish to modify the currently installed axis ticker, access it via ticker.
Since the ticker is stored in the axis as a shared pointer, multiple axes may share the same axis ticker simply by passing the same shared pointer to multiple axes.

See also

ticker

17.660.4.62 setTickLabelColor()

```
void QCPPolarAxisAngular::setTickLabelColor (
            const QColor & color )
```

Sets the color of the tick labels.

See also

setTickLabels, setTickLabelFont

17.660.4.63 setTickLabelFont()

```
void QCPPolarAxisAngular::setTickLabelFont (
            const QFont & font )
```

Sets the font of the tick labels.

See also

setTickLabels, setTickLabelColor

17.660.4.64 setTickLabelPadding()

```
void QCPPolarAxisAngular::setTickLabelPadding (
            int padding )
```

Sets the distance between the axis base line (including any outward ticks) and the tick labels.

See also

setLabelPadding, setPadding

17.660.4.65 setTickLabelRotation()

```
void QCPPolarAxisAngular::setTickLabelRotation (
            double degrees )
```

Sets the rotation of the tick labels. If *degrees* is zero, the labels are drawn normally. Else, the tick labels are drawn rotated by *degrees* clockwise. The specified angle is bound to values from -90 to 90 degrees.
If *degrees* is exactly -90, 0 or 90, the tick labels are centered on the tick coordinate. For other angles, the label is drawn with an offset such that it seems to point toward or away from the tick mark.

17.660.4.66 setTickLabels()

```
void QCPPolarAxisAngular::setTickLabels (
            bool show )
```

Sets whether tick labels are displayed. Tick labels are the numbers drawn next to tick marks.

17.660.4.67 setTickLength()

```
void QCPPolarAxisAngular::setTickLength (
            int inside,
            int outside = 0 )
```

Sets the length of the ticks in pixels. *inside* is the length the ticks will reach inside the plot and *outside* is the length they will reach outside the plot. If *outside* is greater than zero, the tick labels and axis label will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setSubTickLength, setTickLengthIn, setTickLengthOut

17.660.4.68 setTickLengthIn()

```
void QCPPolarAxisAngular::setTickLengthIn (
            int inside )
```

Sets the length of the inward ticks in pixels. *inside* is the length the ticks will reach inside the plot.

See also

setTickLengthOut, setTickLength, setSubTickLength

17.660.4.69 setTickLengthOut()

```
void QCPPolarAxisAngular::setTickLengthOut (
            int outside )
```

Sets the length of the outward ticks in pixels. *outside* is the length the ticks will reach outside the plot. If *outside* is greater than zero, the tick labels and axis label will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setTickLengthIn, setTickLength, setSubTickLength

17.660.4.70 setTickPen()

```
void QCPPolarAxisAngular::setTickPen (
            const QPen & pen )
```

Sets the pen, tick marks will be drawn with.

See also

setTickLength, setBasePen

17.660.4.71 setTicks()

```
void QCPPolarAxisAngular::setTicks (
            bool show )
```

Sets whether tick marks are displayed.
Note that setting *show* to false does not imply that tick labels are invisible, too. To achieve that, see setTickLabels.

See also

setSubTicks

17.660.4.72 size()

```
QSize QCPPolarAxisAngular::size ( ) const  [inline]
```

Returns the pixel size of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.73 top()

```
int QCPPolarAxisAngular::top ( ) const  [inline]
```

Returns the pixel position of the top border of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.74 topLeft()

```
QPoint QCPPolarAxisAngular::topLeft ( ) const  [inline]
```

Returns the top left corner of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.75 topRight()

```
QPoint QCPPolarAxisAngular::topRight ( ) const  [inline]
```

Returns the top right corner of this axis rect in pixels. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.660.4.76 update()

```
void QCPPolarAxisAngular::update (
            UpdatePhase phase )  [virtual]
```

This method is called automatically upon replot and doesn't need to be called by users of QCPPolarAxisAngular.
Calls the base class implementation to update the margins (see QCPLayoutElement::update), and finally passes the rect to the inset layout (insetLayout) and calls its QCPInsetLayout::update function.
\seebaseclassmethod
Reimplemented from QCPLayoutElement.

17.660.4.77 wheelEvent()

```
void QCPPolarAxisAngular::wheelEvent (
            QWheelEvent * event )  [protected], [virtual]
```

This event gets called when the user turns the mouse scroll wheel while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`.
The `event->angleDelta()` indicates how far the mouse wheel was turned, which is usually +/- 120 for single rotation steps. However, if the mouse wheel is turned rapidly, multiple steps may accumulate to one event, making the delta larger. On the other hand, if the wheel has very smooth steps or none at all, the delta may be smaller.
The default implementation does nothing.

mousePressEvent, mouseMoveEvent, mouseReleaseEvent, mouseDoubleClickEvent

Reimplemented from QCPLayerable.

17.660.4.78 width()

```
int QCPPolarAxisAngular::width ( ) const  [inline]
```

Returns the pixel width of this axis rect. Margins are not taken into account here, so the returned value is with respect to the inner rect.

17.661.1 Detailed Description

The radial axis inside a radial plot.

Warning

> In this QCustomPlot version, polar plots are a tech preview. Expect documentation and functionality to be incomplete, as well as changing public interfaces in the future.

Each axis holds an instance of QCPAxisTicker which is used to generate the tick coordinates and tick labels. You can access the currently installed ticker or set a new one (possibly one of the specialized subclasses, or your own subclass) via setTicker. For details, see the documentation of QCPAxisTicker.

17.661.2 Member Enumeration Documentation

17.661.2.1 AngleReference

enum QCPPolarAxisRadial::AngleReference

Defines the reference of the angle at which a radial axis is tilted (setAngle).

Enumerator

arAbsolute	The axis tilt is given in absolute degrees. The zero is to the right and positive angles are measured counter-clockwise.
arAngularAxis	The axis tilt is measured in the angular coordinate system given by the parent angular axis.

17.661.2.2 ScaleType

`enum QCPPolarAxisRadial::ScaleType`
Defines the scale of an axis.

See also

setScaleType

Enumerator

stLinear	Linear scaling.
stLogarithmic	Logarithmic scaling with correspondingly transformed axis coordinates (possibly also setTicker to a QCPAxisTickerLog instance).

17.661.2.3 SelectablePart

`enum QCPPolarAxisRadial::SelectablePart`
Defines the selectable parts of an axis.

See also

setSelectableParts, setSelectedParts

Enumerator

spNone	None of the selectable parts.
spAxis	The axis backbone and tick marks.
spTickLabels	Tick labels (numbers) of this axis (as a whole, not individually)
spAxisLabel	The axis label.

17.661.3 Constructor & Destructor Documentation

17.661.3.1 QCPPolarAxisRadial()

```
QCPPolarAxisRadial::QCPPolarAxisRadial (
            QCPPolarAxisAngular * parent )  [explicit]
```
Constructs an Axis instance of Type *type* for the axis rect *parent*.
Usually it isn't necessary to instantiate axes directly, because you can let QCustomPlot create them for you with QCPAxisRect::addAxis. If you want to use own QCPAxis-subclasses however, create them manually and then inject them also via QCPAxisRect::addAxis.

17.661.4 Member Function Documentation

17.661.4.1 applyDefaultAntialiasingHint()

```
void QCPPolarAxisRadial::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```
Implements QCPLayerable.

17.661.4.2 coordToPixel()

```
QPointF QCPPolarAxisRadial::coordToPixel (
            double angleCoord,
            double radiusCoord ) const
```

Transforms *value*, in coordinates of the axis, to pixel coordinates of the QCustomPlot widget.

17.661.4.3 deselectEvent()

```
void QCPPolarAxisRadial::deselectEvent (
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.661.4.4 draw()

```
void QCPPolarAxisRadial::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPLayerable.

17.661.4.5 getPartAt()

```
QCPPolarAxisRadial::SelectablePart QCPPolarAxisRadial::getPartAt (
            const QPointF & pos ) const
```

Returns the part of the axis that is hit by *pos* (in pixels). The return value of this function is independent of the user-selectable parts defined with setSelectableParts. Further, this function does not change the current selection state of the axis.
If the axis is not visible (setVisible), this function always returns spNone.

See also

setSelectedParts, setSelectableParts, QCustomPlot::setInteractions

17.661.4.6 mouseMoveEvent()

```
void QCPPolarAxisRadial::mouseMoveEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user moves the mouse while holding a mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.661.4.7 mousePressEvent()

```
void QCPPolarAxisRadial::mousePressEvent (
            QMouseEvent * event,
            const QVariant & details )  [protected], [virtual]
```

This event gets called when the user presses a mouse button while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *details* contains layerable-specific details about the hit, which were generated in the previous call to selectTest. For example, One-dimensional plottables like QCPGraph or QCPBars convey the clicked data point in the *details* parameter, as QCPDataSelection packed as QVariant. Multi-part objects convey the specific `SelectablePart` that was hit (e.g. QCPAxis::SelectablePart in the case of axes).

QCustomPlot uses an event propagation system that works the same as Qt's system. If your layerable doesn't reimplement the mousePressEvent or explicitly calls `event->ignore()` in its reimplementation, the event will be propagated to the next layerable in the stacking order.
Once a layerable has accepted the mousePressEvent, it is considered the mouse grabber and will receive all following calls to mouseMoveEvent or mouseReleaseEvent for this mouse interaction (a "mouse interaction" in this context ends with the release).
The default implementation does nothing except explicitly ignoring the event with `event->ignore()`.

See also

mouseMoveEvent, mouseReleaseEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.661.4.8 mouseReleaseEvent()

```
void QCPPolarAxisRadial::mouseReleaseEvent (
            QMouseEvent * event,
            const QPointF & startPos )  [protected], [virtual]
```

This event gets called when the user releases the mouse button, after this layerable has become the mouse grabber by accepting the preceding mousePressEvent.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`. The parameter *startPos* indicates the position where the initial mousePressEvent occurred, that started the mouse interaction.
The default implementation does nothing.

See also

mousePressEvent, mouseMoveEvent, mouseDoubleClickEvent, wheelEvent

Reimplemented from QCPLayerable.

17.661.4.9 moveRange()

```
void QCPPolarAxisRadial::moveRange (
            double diff )
```

If the scale type (setScaleType) is stLinear, *diff* is added to the lower and upper bounds of the range. The range is simply moved by *diff*.
If the scale type is stLogarithmic, the range bounds are multiplied by *diff*. This corresponds to an apparent "linear" move in logarithmic scaling by a distance of log(diff).

17.661.4.10 pixelToCoord()

```
void QCPPolarAxisRadial::pixelToCoord (
            QPointF pixelPos,
            double & angleCoord,
            double & radiusCoord ) const
```

Transforms *value*, in pixel coordinates of the QCustomPlot widget, to axis coordinates.

17.661.4.11 rangeChanged [1/2]

```
void QCPPolarAxisRadial::rangeChanged (
            const QCPRange & newRange )  [signal]
```

This signal is emitted when the range of this axis has changed. You can connect it to the setRange slot of another axis to communicate the new range to the other axis, in order for it to be synchronized.
You may also manipulate/correct the range with setRange in a slot connected to this signal. This is useful if for example a maximum range span shall not be exceeded, or if the lower/upper range shouldn't go beyond certain values (see QCPRange::bounded). For example, the following slot would limit the x axis to ranges between 0 and 10:

```
customPlot->xAxis->setRange(newRange.bounded(0, 10))
```

17.661.4.12 rangeChanged [2/2]

```
void QCPPolarAxisRadial::rangeChanged (
            const QCPRange & newRange,
            const QCPRange & oldRange )  [signal]
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Additionally to the new range, this signal also provides the previous range held by the axis as *oldRange*.

17.661.4.13 rescale()

```
void QCPPolarAxisRadial::rescale (
            bool onlyVisiblePlottables = false )
```

Changes the axis range such that all plottables associated with this axis are fully visible in that dimension.

See also

QCPAbstractPlottable::rescaleAxes, QCustomPlot::rescaleAxes

17.661.4.14 scaleRange() [1/2]

```
void QCPPolarAxisRadial::scaleRange (
            double factor )
```

Scales the range of this axis by *factor* around the center of the current axis range. For example, if *factor* is 2.0, then the axis range will double its size, and the point at the axis range center won't have changed its position in the QCustomPlot widget (i.e. coordinates around the center will have moved symmetrically closer).
If you wish to scale around a different coordinate than the current axis range center, use the overload scaleRange(double factor, double center).

17.661.4.15 scaleRange() [2/2]

```
void QCPPolarAxisRadial::scaleRange (
            double factor,
            double center )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Scales the range of this axis by *factor* around the coordinate *center*. For example, if *factor* is 2.0, *center* is 1.0, then the axis range will double its size, and the point at coordinate 1.0 won't have changed its position in the QCustomPlot widget (i.e. coordinates around 1.0 will have moved symmetrically closer to 1.0).

See also

scaleRange(double factor)

17.661.4.16 scaleTypeChanged

```
void QCPPolarAxisRadial::scaleTypeChanged (
            QCPPolarAxisRadial::ScaleType scaleType )  [signal]
```

This signal is emitted when the scale type changes, by calls to setScaleType

17.661.4.17 selectableChanged

```
void QCPPolarAxisRadial::selectableChanged (
            const QCPPolarAxisRadial::SelectableParts & parts )  [signal]
```

This signal is emitted when the selectability changes, by calls to setSelectableParts

17.661.4.18 selectEvent()

```
void QCPPolarAxisRadial::selectEvent (
            QMouseEvent * event,
            bool additive,
            const QVariant & details,
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.661.4.19 selectionCategory()

```
QCP::Interaction QCPPolarAxisRadial::selectionCategory ( ) const  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.661.4.20 selectionChanged

```
void QCPPolarAxisRadial::selectionChanged (
            const QCPPolarAxisRadial::SelectableParts & parts )  [signal]
```

This signal is emitted when the selection state of this axis has changed, either by user interaction or by a direct call to setSelectedParts.

17.661.4.21 selectTest()

```
double QCPPolarAxisRadial::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = 0 ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.
pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

See also

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Reimplemented from QCPLayerable.

17.661.4.22 setBasePen()

```
void QCPPolarAxisRadial::setBasePen (
            const QPen & pen )
```

Sets the pen, the axis base line is drawn with.

See also

setTickPen, setSubTickPen

17.661.4.23 setLabel()

```
void QCPPolarAxisRadial::setLabel (
            const QString & str )
```

Sets the text of the axis label that will be shown below/above or next to the axis, depending on its orientation. To disable axis labels, pass an empty string as *str*.

17.661.4.24 setLabelColor()

```
void QCPPolarAxisRadial::setLabelColor (
            const QColor & color )
```

Sets the color of the axis label.

See also

setLabelFont

17.661.4.25 setLabelFont()

```
void QCPPolarAxisRadial::setLabelFont (
            const QFont & font )
```

Sets the font of the axis label.

See also

setLabelColor

17.661.4.26 setLabelPadding()

```
void QCPPolarAxisRadial::setLabelPadding (
            int padding )
```

Sets the distance between the tick labels and the axis label.

See also

setTickLabelPadding, setPadding

17.661.4.27 setNumberFormat()

```
void QCPPolarAxisRadial::setNumberFormat (
            const QString & formatCode )
```

Sets the number format for the numbers in tick labels. This *formatCode* is an extended version of the format code used e.g. by QString::number() and QLocale::toString(). For reference about that, see the "Argument Formats" section in the detailed description of the QString class.
formatCode is a string of one, two or three characters. The first character is identical to the normal format code used by Qt. In short, this means: 'e'/'E' scientific format, 'f' fixed format, 'g'/'G' scientific or fixed, whichever is shorter.
The second and third characters are optional and specific to QCustomPlot:
If the first char was 'e' or 'g', numbers are/might be displayed in the scientific format, e.g. "5.5e9", which is ugly in a plot. So when the second char of *formatCode* is set to 'b' (for "beautiful"), those exponential numbers are formatted in a more natural way, i.e. "5.5 [multiplication sign] 10 [superscript] 9". By default, the multiplication sign is a centered dot. If instead a cross should be shown (as is usual in the USA), the third char of *formatCode* can be set to 'c'. The inserted multiplication signs are the UTF-8 characters 215 (0xD7) for the cross and 183 (0xB7) for the dot.
Examples for *formatCode:*

- `g` normal format code behaviour. If number is small, fixed format is used, if number is large, normal scientific format is used

- `gb` If number is small, fixed format is used, if number is large, scientific format is used with beautifully typeset decimal powers and a dot as multiplication sign
- `ebc` All numbers are in scientific format with beautifully typeset decimal power and a cross as multiplication sign
- `fb` illegal format code, since fixed format doesn't support (or need) beautifully typeset decimal powers. Format code will be reduced to 'f'.
- `hello` illegal format code, since first char is not 'e', 'E', 'f', 'g' or 'G'. Current format code will not be changed.

17.661.4.28 setNumberPrecision()

```
void QCPPolarAxisRadial::setNumberPrecision (
            int precision )
```

Sets the precision of the tick label numbers. See QLocale::toString(double i, char f, int prec) for details. The effect of precisions are most notably for number Formats starting with 'e', see setNumberFormat

17.661.4.29 setRange() [1/3]

```
void QCPPolarAxisRadial::setRange (
            const QCPRange & range )
```

Sets the range of the axis.
This slot may be connected with the rangeChanged signal of another axis so this axis is always synchronized with the other axis range, when it changes.
To invert the direction of an axis, use setRangeReversed.

17.661.4.30 setRange() [2/3]

```
void QCPPolarAxisRadial::setRange (
            double lower,
            double upper )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the lower and upper bound of the axis range.
To invert the direction of an axis, use setRangeReversed.
There is also a slot to set a range, see setRange(const QCPRange &range).

17.661.4.31 setRange() [3/3]

```
void QCPPolarAxisRadial::setRange (
            double position,
            double size,
            Qt::AlignmentFlag alignment )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Sets the range of the axis.
The *position* coordinate indicates together with the *alignment* parameter, where the new range will be positioned. *size* defines the size of the new axis range. *alignment* may be Qt::AlignLeft, Qt::AlignRight or Qt::AlignCenter. This will cause the left border, right border, or center of the range to be aligned with *position*. Any other values of *alignment* will default to Qt::AlignCenter.

17.661.4.32 setRangeLower()

```
void QCPPolarAxisRadial::setRangeLower (
            double lower )
```

Sets the lower bound of the axis range. The upper bound is not changed.

See also

setRange

17.661.4.33 setRangeReversed()

```
void QCPPolarAxisRadial::setRangeReversed (
            bool reversed )
```

Sets whether the axis range (direction) is displayed reversed. Normally, the values on horizontal axes increase left to right, on vertical axes bottom to top. When *reversed* is set to true, the direction of increasing values is inverted.
Note that the range and data interface stays the same for reversed axes, e.g. the *lower* part of the setRange interface will still reference the mathematically smaller number than the *upper* part.

17.661.4.34 setRangeUpper()

```
void QCPPolarAxisRadial::setRangeUpper (
            double upper )
```

Sets the upper bound of the axis range. The lower bound is not changed.

See also

setRange

17.661.4.35 setScaleType()

```
void QCPPolarAxisRadial::setScaleType (
            QCPPolarAxisRadial::ScaleType type )
```

Sets whether the axis uses a linear scale or a logarithmic scale.
Note that this method controls the coordinate transformation. For logarithmic scales, you will likely also want to use a logarithmic tick spacing and labeling, which can be achieved by setting the axis ticker to an instance of QCPAxisTickerLog :
See the documentation of QCPAxisTickerLog about the details of logarithmic axis tick creation.
setNumberPrecision

17.661.4.36 setSelectableParts()

```
void QCPPolarAxisRadial::setSelectableParts (
            const QCPPolarAxisRadial::SelectableParts & selectableParts )
```

Sets whether the user can (de-)select the parts in *selectable* by clicking on the QCustomPlot surface. (When QCustomPlot::setInteractions contains iSelectAxes.)
However, even when *selectable* is set to a value not allowing the selection of a specific part, it is still possible to set the selection of this part manually, by calling setSelectedParts directly.

See also

SelectablePart, setSelectedParts

17.661.4.37 setSelectedBasePen()

```
void QCPPolarAxisRadial::setSelectedBasePen (
            const QPen & pen )
```

Sets the pen that is used to draw the axis base line when selected.

See also

setBasePen, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.661.4.38 setSelectedLabelColor()

```
void QCPPolarAxisRadial::setSelectedLabelColor (
            const QColor & color )
```

Sets the color that is used for the axis label when it is selected.

See also

setLabelColor, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.661.4.39 setSelectedLabelFont()

```
void QCPPolarAxisRadial::setSelectedLabelFont (
            const QFont & font )
```

Sets the font that is used for the axis label when it is selected.

See also

setLabelFont, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.661.4.40 setSelectedParts()

```
void QCPPolarAxisRadial::setSelectedParts (
            const QCPPolarAxisRadial::SelectableParts & selectedParts )
```

Sets the selected state of the respective axis parts described by SelectablePart. When a part is selected, it uses a different pen/font.
The entire selection mechanism for axes is handled automatically when QCustomPlot::setInteractions contains iSelectAxes. You only need to call this function when you wish to change the selection state manually.
This function can change the selection state of a part, independent of the setSelectableParts setting.
emits the selectionChanged signal when *selected* is different from the previous selection state.

See also

SelectablePart, setSelectableParts, selectTest, setSelectedBasePen, setSelectedTickPen, setSelectedSubTickPen, setSelectedTickLabelFont, setSelectedLabelFont, setSelectedTickLabelColor, setSelectedLabelColor

17.661.4.41 setSelectedSubTickPen()

```
void QCPPolarAxisRadial::setSelectedSubTickPen (
            const QPen & pen )
```

Sets the pen that is used to draw the subticks when selected.

See also

setSubTickPen, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.661.4.42 setSelectedTickLabelColor()

```
void QCPPolarAxisRadial::setSelectedTickLabelColor (
            const QColor & color )
```

Sets the color that is used for tick labels when they are selected.

See also

setTickLabelColor, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.661.4.43 setSelectedTickLabelFont()

```
void QCPPolarAxisRadial::setSelectedTickLabelFont (
            const QFont & font )
```

Sets the font that is used for tick labels when they are selected.

See also

setTickLabelFont, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.661.4.44 setSelectedTickPen()

```
void QCPPolarAxisRadial::setSelectedTickPen (
            const QPen & pen )
```

Sets the pen that is used to draw the (major) ticks when selected.

See also

setTickPen, setSelectableParts, setSelectedParts, QCustomPlot::setInteractions

17.661.4.45 setSubTickLength()

```
void QCPPolarAxisRadial::setSubTickLength (
            int inside,
            int outside = 0 )
```

Sets the length of the subticks in pixels. *inside* is the length the subticks will reach inside the plot and *outside* is the length they will reach outside the plot. If *outside* is greater than zero, the tick labels and axis label will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setTickLength, setSubTickLengthIn, setSubTickLengthOut

17.661.4.46 setSubTickLengthIn()

```
void QCPPolarAxisRadial::setSubTickLengthIn (
            int inside )
```

Sets the length of the inward subticks in pixels. *inside* is the length the subticks will reach inside the plot.

See also

setSubTickLengthOut, setSubTickLength, setTickLength

17.661.4.47 setSubTickLengthOut()

```
void QCPPolarAxisRadial::setSubTickLengthOut (
            int outside )
```

Sets the length of the outward subticks in pixels. *outside* is the length the subticks will reach outside the plot. If *outside* is greater than zero, the tick labels will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setSubTickLengthIn, setSubTickLength, setTickLength

17.661.4.48 setSubTickPen()

```
void QCPPolarAxisRadial::setSubTickPen (
            const QPen & pen )
```

Sets the pen, subtick marks will be drawn with.

See also

setSubTickCount, setSubTickLength, setBasePen

17.661.4.49 setSubTicks()

```
void QCPPolarAxisRadial::setSubTicks (
            bool show )
```

Sets whether sub tick marks are displayed.
Sub ticks are only potentially visible if (major) ticks are also visible (see setTicks)

See also

setTicks

17.661.4.50 setTicker()

```
void QCPPolarAxisRadial::setTicker (
            QSharedPointer< QCPAxisTicker > ticker )
```

The axis ticker is responsible for generating the tick positions and tick labels. See the documentation of QCPAxisTicker for details on how to work with axis tickers.
You can change the tick positioning/labeling behaviour of this axis by setting a different QCPAxisTicker subclass using this method. If you only wish to modify the currently installed axis ticker, access it via ticker.
Since the ticker is stored in the axis as a shared pointer, multiple axes may share the same axis ticker simply by passing the same shared pointer to multiple axes.

See also

ticker

17.661.4.51 setTickLabelColor()

```
void QCPPolarAxisRadial::setTickLabelColor (
            const QColor & color )
```

Sets the color of the tick labels.

See also

setTickLabels, setTickLabelFont

17.661.4.52 setTickLabelFont()

```
void QCPPolarAxisRadial::setTickLabelFont (
            const QFont & font )
```

Sets the font of the tick labels.

See also

setTickLabels, setTickLabelColor

17.661.4.53 setTickLabelPadding()

```
void QCPPolarAxisRadial::setTickLabelPadding (
            int padding )
```

Sets the distance between the axis base line (including any outward ticks) and the tick labels.

See also

setLabelPadding, setPadding

17.661.4.54 setTickLabelRotation()

```
void QCPPolarAxisRadial::setTickLabelRotation (
            double degrees )
```

Sets the rotation of the tick labels. If *degrees* is zero, the labels are drawn normally. Else, the tick labels are drawn rotated by *degrees* clockwise. The specified angle is bound to values from -90 to 90 degrees.
If *degrees* is exactly -90, 0 or 90, the tick labels are centered on the tick coordinate. For other angles, the label is drawn with an offset such that it seems to point toward or away from the tick mark.

17.661.4.55 setTickLabels()

```
void QCPPolarAxisRadial::setTickLabels (
            bool show )
```

Sets whether tick labels are displayed. Tick labels are the numbers drawn next to tick marks.

17.661.4.56 setTickLength()

```
void QCPPolarAxisRadial::setTickLength (
            int inside,
            int outside = 0 )
```

Sets the length of the ticks in pixels. *inside* is the length the ticks will reach inside the plot and *outside* is the length they will reach outside the plot. If *outside* is greater than zero, the tick labels and axis label will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setSubTickLength, setTickLengthIn, setTickLengthOut

17.661.4.57 setTickLengthIn()

```
void QCPPolarAxisRadial::setTickLengthIn (
            int inside )
```

Sets the length of the inward ticks in pixels. *inside* is the length the ticks will reach inside the plot.

See also

setTickLengthOut, setTickLength, setSubTickLength

17.661.4.58 setTickLengthOut()

```
void QCPPolarAxisRadial::setTickLengthOut (
            int outside )
```

Sets the length of the outward ticks in pixels. *outside* is the length the ticks will reach outside the plot. If *outside* is greater than zero, the tick labels and axis label will increase their distance to the axis accordingly, so they won't collide with the ticks.

See also

setTickLengthIn, setTickLength, setSubTickLength

17.661.4.59 setTickPen()

```
void QCPPolarAxisRadial::setTickPen (
            const QPen & pen )
```

Sets the pen, tick marks will be drawn with.

See also

setTickLength, setBasePen

17.661.4.60 setTicks()

```
void QCPPolarAxisRadial::setTicks (
            bool show )
```

Sets whether tick marks are displayed.
Note that setting *show* to false does not imply that tick labels are invisible, too. To achieve that, see setTickLabels.

See also

setSubTicks

17.661.4.61 ticker()

```
QSharedPointer< QCPAxisTicker > QCPPolarAxisRadial::ticker ( ) const  [inline]
```

Returns a modifiable shared pointer to the currently installed axis ticker. The axis ticker is responsible for generating the tick positions and tick labels of this axis. You can access the QCPAxisTicker with this method and modify basic properties such as the approximate tick count (QCPAxisTicker::setTickCount).
You can gain more control over the axis ticks by setting a different QCPAxisTicker subclass, see the documentation there. A new axis ticker can be set with setTicker.
Since the ticker is stored in the axis as a shared pointer, multiple axes may share the same axis ticker simply by passing the same shared pointer to multiple axes.

See also

setTicker

17.661.4.62 wheelEvent()

```
void QCPPolarAxisRadial::wheelEvent (
            QWheelEvent * event )  [protected], [virtual]
```

This event gets called when the user turns the mouse scroll wheel while the cursor is over the layerable. Whether a cursor is over the layerable is decided by a preceding call to selectTest.
The current pixel position of the cursor on the QCustomPlot widget is accessible via `event->pos()`.
The `event->angleDelta()` indicates how far the mouse wheel was turned, which is usually +/- 120 for single rotation steps. However, if the mouse wheel is turned rapidly, multiple steps may accumulate to one event, making the delta larger. On the other hand, if the wheel has very smooth steps or none at all, the delta may be smaller.
The default implementation does nothing.

17.662.1 Detailed Description

A radial graph used to display data in polar plots.

Warning

> In this QCustomPlot version, polar plots are a tech preview. Expect documentation and functionality to be incomplete, as well as changing public interfaces in the future.

17.662.2 Member Enumeration Documentation

17.662.2.1 LineStyle

`enum QCPPolarGraph::LineStyle`

Defines how the graph's line is represented visually in the plot. The line is drawn with the current pen of the graph (setPen).

See also

> setLineStyle

Enumerator

lsNone	with symbols according to the scatter style, see setScatterStyle) data points are not connected with any lines (e.g. data only represented
lsLine	data points are connected by a straight line

17.662.3 Constructor & Destructor Documentation

17.662.3.1 QCPPolarGraph()

```
QCPPolarGraph::QCPPolarGraph (
            QCPPolarAxisAngular * keyAxis,
            QCPPolarAxisRadial * valueAxis )
```

Constructs a graph which uses *keyAxis* as its angular and *valueAxis* as its radial axis. *keyAxis* and *valueAxis* must reside in the same QCustomPlot, and the radial axis must be associated with the angular axis. If either of these restrictions is violated, a corresponding message is printed to the debug output (qDebug), the construction is not aborted, though.

The created QCPPolarGraph is automatically registered with the QCustomPlot instance inferred from *keyAxis*. This QCustomPlot instance takes ownership of the QCPPolarGraph, so do not delete it manually but use QCPPolar↩ AxisAngular::removeGraph() instead.

To directly create a QCPPolarGraph inside a plot, you shoud use the QCPPolarAxisAngular::addGraph method.

17.662.4 Member Function Documentation

17.662.4.1 applyDefaultAntialiasingHint()

```
void QCPPolarGraph::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Implements QCPLayerable.

17.662.4.2 clipRect()

```
QRect QCPPolarGraph::clipRect ( ) const  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.662.4.3 coordsToPixels()

```
void QCPPolarGraph::coordsToPixels (
            double key,
            double value,
            double & x,
            double & y ) const
```

Use this method to set an own QCPSelectionDecorator (subclass) instance. This allows you to customize the visual representation of selected data ranges further than by using the default QCPSelectionDecorator.
The plottable takes ownership of the *decorator*.
The currently set decorator can be accessed via selectionDecorator.

17.662.4.4 deselectEvent()

```
void QCPPolarGraph::deselectEvent (
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.662.4.5 draw()

```
void QCPPolarGraph::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPLayerable.

17.662.4.6 selectEvent()

```
void QCPPolarGraph::selectEvent (
            QMouseEvent * event,
            bool additive,
            const QVariant & details,
            bool * selectionStateChanged )  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.662.4.7 selectionCategory()

```
QCP::Interaction QCPPolarGraph::selectionCategory ( ) const  [protected], [virtual]
```

Reimplemented from QCPLayerable.

17.662.4.8 selectTest()

```
double QCPPolarGraph::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = 0 ) const  [virtual]
```

This function is used to decide whether a click hits a layerable object or not.

pos is a point in pixel coordinates on the QCustomPlot surface. This function returns the shortest pixel distance of this point to the object. If the object is either invisible or the distance couldn't be determined, -1.0 is returned. Further, if *onlySelectable* is true and the object is not selectable, -1.0 is returned, too.
If the object is represented not by single lines but by an area like a QCPItemText or the bars of a QCPBars plottable, a click inside the area should also be considered a hit. In these cases this function thus returns a constant value greater zero but still below the parent plot's selection tolerance. (typically the selectionTolerance multiplied by 0.99). Providing a constant value for area objects allows selecting line objects even when they are obscured by such area objects, by clicking close to the lines (i.e. closer than 0.99∗selectionTolerance).
The actual setting of the selection state is not done by this function. This is handled by the parent QCustomPlot when the mouseReleaseEvent occurs, and the finally selected object is notified via the selectEvent/ deselectEvent methods.
details is an optional output parameter. Every layerable subclass may place any information in *details*. This information will be passed to selectEvent when the parent QCustomPlot decides on the basis of this selectTest call, that the object was successfully selected. The subsequent call to selectEvent will carry the *details*. This is useful for multi-part objects (like QCPAxis). This way, a possibly complex calculation to decide which part was clicked is only done once in selectTest. The result (i.e. the actually clicked part) can then be placed in *details*. So in the subsequent selectEvent, the decision which part was selected doesn't have to be done a second time for a single selection operation.
In the case of 1D Plottables (QCPAbstractPlottable1D, like QCPGraph or QCPBars) *details* will be set to a QCPDataSelection, describing the closest data point to *pos*.
You may pass `nullptr` as *details* to indicate that you are not interested in those selection details.

selectEvent, deselectEvent, mousePressEvent, wheelEvent, QCustomPlot::setInteractions, QCPAbstractPlottable1D::selectTest

Reimplemented from QCPLayerable.

17.662.4.9 setAntialiasedFill()

```
void QCPPolarGraph::setAntialiasedFill (
            bool enabled )
```

Sets whether fills of this plottable are drawn antialiased or not.
Note that this setting may be overridden by QCustomPlot::setAntialiasedElements and QCustomPlot::setNotAntialiasedElements.

17.662.4.10 setAntialiasedScatters()

```
void QCPPolarGraph::setAntialiasedScatters (
            bool enabled )
```

Sets whether the scatter symbols of this plottable are drawn antialiased or not.
Note that this setting may be overridden by QCustomPlot::setAntialiasedElements and QCustomPlot::setNotAntialiasedElements.

17.662.4.11 setBrush()

```
void QCPPolarGraph::setBrush (
            const QBrush & brush )
```

The brush is used to draw basic fills of the plottable representation in the plot. The Fill can be a color, gradient or texture, see the usage of QBrush.
For example, the QCPGraph subclass draws the fill under the graph with this brush, when it's not set to Qt::NoBrush.

See also

setPen

17.662.4.12 setData() [1/2]

```
void QCPPolarGraph::setData (
            const QVector< double > & keys,
```

```
            const QVector< double > & values,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data with the provided points in *keys* and *values*. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.
If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.

See also

addData

17.662.4.13 setData() [2/2]

```
void QCPPolarGraph::setData (
            QSharedPointer< QCPGraphDataContainer > data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data container with the provided *data* container.
Since a QSharedPointer is used, multiple QCPPolarGraphs may share the same data container safely. Modifying the data in the container will then affect all graphs that share the container. Sharing can be achieved by simply exchanging the data containers wrapped in shared pointers:
If you do not wish to share containers, but create a copy from an existing container, rather use the QCPDataContainer<DataType>::set method on the graph's data container directly:

See also

addData

17.662.4.14 setKeyAxis()

```
void QCPPolarGraph::setKeyAxis (
            QCPPolarAxisAngular * axis )
```

The key axis of a plottable can be set to any axis of a QCustomPlot, as long as it is orthogonal to the plottable's value axis. This function performs no checks to make sure this is the case. The typical mathematical choice is to use the x-axis (QCustomPlot::xAxis) as key axis and the y-axis (QCustomPlot::yAxis) as value axis.
Normally, the key and value axes are set in the constructor of the plottable (or QCustomPlot::addGraph when working with QCPGraphs through the dedicated graph interface).

See also

setValueAxis

17.662.4.15 setLineStyle()

```
void QCPPolarGraph::setLineStyle (
            LineStyle ls )
```

Sets how the single data points are connected in the plot. For scatter-only plots, set *ls* to lsNone and setScatterStyle to the desired scatter style.

See also

setScatterStyle

17.662.4.16 setName()

```
void QCPPolarGraph::setName (
            const QString & name )
```

The name is the textual representation of this plottable as it is displayed in the legend (QCPLegend). It may contain any UTF-8 characters, including newlines.

17.662.4.17 setPen()

```
void QCPPolarGraph::setPen (
            const QPen & pen )
```

The pen is used to draw basic lines that make up the plottable representation in the plot.
For example, the QCPGraph subclass draws its graph lines with this pen.

See also

setBrush

17.662.4.18 setScatterStyle()

```
void QCPPolarGraph::setScatterStyle (
            const QCPScatterStyle & style )
```

Sets the visual appearance of single data points in the plot. If set to QCPScatterStyle::ssNone, no scatter points are drawn (e.g. for line-only-plots with appropriate line style).

See also

QCPScatterStyle, setLineStyle

17.662.4.19 setSelectable()

```
void QCPPolarGraph::setSelectable (
            QCP::SelectionType selectable )
```

Sets whether and to which granularity this plottable can be selected.
A selection can happen by clicking on the QCustomPlot surface (When QCustomPlot::setInteractions contains QCP::iSelectPlottables), by dragging a selection rect (When QCustomPlot::setSelectionRectMode is QCP::srmSelect), or programmatically by calling setSelection.

See also

setSelection, QCP::SelectionType

17.662.4.20 setSelection()

```
void QCPPolarGraph::setSelection (
            QCPDataSelection selection )
```

Sets which data ranges of this plottable are selected. Selected data ranges are drawn differently (e.g. color) in the plot. This can be controlled via the selection decorator (see selectionDecorator).
The entire selection mechanism for plottables is handled automatically when QCustomPlot::setInteractions contains iSelectPlottables. You only need to call this function when you wish to change the selection state programmatically. Using setSelectable you can further specify for each plottable whether and to which granularity it is selectable. If *selection* is not compatible with the current QCP::SelectionType set via setSelectable, the resulting selection will be adjusted accordingly (see QCPDataSelection::enforceType).
emits the selectionChanged signal when *selected* is different from the previous selection state.

See also

setSelectable, selectTest

17.662.4.21 setValueAxis()

```
void QCPPolarGraph::setValueAxis (
            QCPPolarAxisRadial * axis )
```

The value axis of a plottable can be set to any axis of a QCustomPlot, as long as it is orthogonal to the plottable's key axis. This function performs no checks to make sure this is the case. The typical mathematical choice is to use the x-axis (QCustomPlot::xAxis) as key axis and the y-axis (QCustomPlot::yAxis) as value axis.
Normally, the key and value axes are set in the constructor of the plottable (or QCustomPlot::addGraph when working with QCPGraphs through the dedicated graph interface).

17.663.1 Detailed Description

The grid in both angular and radial dimensions for polar plots.

Warning

> In this QCustomPlot version, polar plots are a tech preview. Expect documentation and functionality to be incomplete, as well as changing public interfaces in the future.

17.663.2 Member Enumeration Documentation

17.663.2.1 GridType

```
enum QCPPolarGrid::GridType
```

TODO

17.663.3 Constructor & Destructor Documentation

17.663.3.1 QCPPolarGrid()

```
QCPPolarGrid::QCPPolarGrid (
            QCPPolarAxisAngular * parentAxis )  [explicit]
```

Creates a QCPPolarGrid instance and sets default values.
You shouldn't instantiate grids on their own, since every axis brings its own grid.

17.663.4 Member Function Documentation

17.663.4.1 applyDefaultAntialiasingHint()

```
void QCPPolarGrid::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Implements QCPLayerable.

17.663.4.2 draw()

```
void QCPPolarGrid::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPLayerable.

17.663.4.3 setAngularPen()

```
void QCPPolarGrid::setAngularPen (
            const QPen & pen )
```

Sets the pen with which (major) grid lines are drawn.

17.663.4.4 setAngularSubGridPen()

```
void QCPPolarGrid::setAngularSubGridPen (
            const QPen & pen )
```

Sets the pen with which sub grid lines are drawn.

17.663.4.5 setAntialiasedSubGrid()

```
void QCPPolarGrid::setAntialiasedSubGrid (
            bool enabled )
```

Sets whether sub grid lines are drawn antialiased.

17.663.4.6 setAntialiasedZeroLine()

```
void QCPPolarGrid::setAntialiasedZeroLine (
            bool enabled )
```

Sets whether zero lines are drawn antialiased.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.664.1 Detailed Description

A legend item for polar plots.

Warning

> In this QCustomPlot version, polar plots are a tech preview. Expect documentation and functionality to be incomplete, as well as changing public interfaces in the future.

17.664.2 Member Function Documentation

17.664.2.1 draw()

```
void QCPPolarLegendItem::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractLegendItem.

17.664.2.2 minimumOuterSizeHint()

```
QSize QCPPolarLegendItem::minimumOuterSizeHint ( ) const  [protected], [virtual]
```

Returns the suggested minimum size this layout element (the outerRect) may be compressed to, if no manual minimum size is set.
if a minimum size (setMinimumSize) was not set manually, parent layouts use the returned size (usually indirectly through QCPLayout::getFinalMinimumOuterSize) to determine the minimum allowed size of this layout element.
A manual minimum size is considered set if it is non-zero.
The default implementation simply returns the sum of the horizontal margins for the width and the sum of the vertical margins for the height. Reimplementations may use their detailed knowledge about the layout element's content to provide size hints.
Reimplemented from QCPLayoutElement.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.665.1 Detailed Description

Represents the range an axis is encompassing.
contains a *lower* and *upper* double value and provides convenience input, output and modification functions.

See also

QCPAxis::setRange

17.665.2 Constructor & Destructor Documentation

17.665.2.1 QCPRange() [1/2]

```
QCPRange::QCPRange ( )
```

Constructs a range with *lower* and *upper* set to zero.

17.665.2.2 QCPRange() [2/2]

```
QCPRange::QCPRange (
            double lower,
            double upper )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Constructs a range with the specified *lower* and *upper* values.
The resulting range will be normalized (see normalize), so if *lower* is not numerically smaller than *upper*, they will be swapped.

17.665.3 Member Function Documentation

17.665.3.1 bounded()

```
QCPRange QCPRange::bounded (
            double lowerBound,
            double upperBound ) const
```

Returns this range, possibly modified to not exceed the bounds provided as *lowerBound* and *upperBound*. If possible, the size of the current range is preserved in the process.

If the range shall only be bounded at the lower side, you can set *upperBound* to QCPRange::maxRange. If it shall only be bounded at the upper side, set *lowerBound* to -QCPRange::maxRange.

17.665.3.2 center()

```
double QCPRange::center ( ) const  [inline]
```

Returns the center of the range, i.e. (*upper+lower)∗0.5*

17.665.3.3 contains()

```
bool QCPRange::contains (
            double value ) const  [inline]
```

Returns true when *value* lies within or exactly on the borders of the range.

17.665.3.4 expand() [1/2]

```
void QCPRange::expand (
            const QCPRange & otherRange )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Expands this range such that *otherRange* is contained in the new range. It is assumed that both this range and *otherRange* are normalized (see normalize).
If this range contains NaN as lower or upper bound, it will be replaced by the respective bound of *otherRange*.
If *otherRange* is already inside the current range, this function does nothing.

See also

expanded

17.665.3.5 expand() [2/2]

```
void QCPRange::expand (
            double includeCoord )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Expands this range such that *includeCoord* is contained in the new range. It is assumed that this range is normalized (see normalize).
If this range contains NaN as lower or upper bound, the respective bound will be set to *includeCoord*.
If *includeCoord* is already inside the current range, this function does nothing.

See also

expand

17.665.3.6 expanded() [1/2]

```
QCPRange QCPRange::expanded (
            const QCPRange & otherRange ) const
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Returns an expanded range that contains this and *otherRange*. It is assumed that both this range and *otherRange* are normalized (see normalize).
If this range contains NaN as lower or upper bound, the returned range's bound will be taken from *otherRange*.

See also

expand

17.665.3.7 expanded() [2/2]

```
QCPRange QCPRange::expanded (
            double includeCoord ) const
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Returns an expanded range that includes the specified *includeCoord*. It is assumed that this range is normalized (see normalize).
If this range contains NaN as lower or upper bound, the returned range's bound will be set to *includeCoord*.

See also

expand

17.665.3.8 normalize()

```
void QCPRange::normalize ( )  [inline]
```

Makes sure *lower* is numerically smaller than *upper*. If this is not the case, the values are swapped.

17.665.3.9 operator*=()

```
QCPRange & QCPRange::operator*= (
            const double & value )  [inline]
```

Multiplies both boundaries of the range by *value*.

17.665.3.10 operator+=()

```
QCPRange & QCPRange::operator+= (
            const double & value )  [inline]
```

Adds *value* to both boundaries of the range.

17.665.3.11 operator-=()

```
QCPRange & QCPRange::operator-= (
            const double & value )  [inline]
```

Subtracts *value* from both boundaries of the range.

17.665.3.12 operator/=()

```
QCPRange & QCPRange::operator/= (
            const double & value )  [inline]
```

Divides both boundaries of the range by *value*.

17.665.3.13 sanitizedForLinScale()

```
QCPRange QCPRange::sanitizedForLinScale ( ) const
```

Returns a sanitized version of the range. Sanitized means for linear scales, that *lower* will always be numerically smaller (or equal) to *upper*.

17.665.3.14 sanitizedForLogScale()

```
QCPRange QCPRange::sanitizedForLogScale ( ) const
```

Returns a sanitized version of the range. Sanitized means for logarithmic scales, that the range won't span the positive and negative sign domain, i.e. contain zero. Further *lower* will always be numerically smaller (or equal) to *upper*.
If the original range does span positive and negative sign domains or contains zero, the returned range will try to approximate the original range as good as possible. If the positive interval of the original range is wider than the negative interval, the returned range will only contain the positive interval, with lower bound set to *rangeFac* or *rangeFac* ∗*upper*, whichever is closer to zero. Same procedure is used if the negative interval is wider than the positive interval, this time by changing the *upper* bound.

17.665.3.15 size()

```
double QCPRange::size ( ) const  [inline]
```
Returns the size of the range, i.e. *upper-lower*

17.665.3.16 validRange() [1/2]

```
bool QCPRange::validRange (
            const QCPRange & range )  [static]
```
This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. Checks, whether the specified range is within valid bounds, which are defined as QCPRange::maxRange and QCPRange::minRange. A valid range means:

- range bounds within -maxRange and maxRange
- range size above minRange
- range size below maxRange

17.665.3.17 validRange() [2/2]

```
bool QCPRange::validRange (
            double lower,
            double upper )  [static]
```
Checks, whether the specified range is within valid bounds, which are defined as QCPRange::maxRange and QCPRange::minRange. A valid range means:

- range bounds within -maxRange and maxRange
- range size above minRange
- range size below maxRange

17.665.4 Friends And Related Symbol Documentation

17.665.4.1 operator* [1/2]

```
const QCPRange operator* (
            const QCPRange & range,
            double value )  [friend]
```
Multiplies both boundaries of the range by *value*.

17.665.4.2 operator* [2/2]

```
const QCPRange operator* (
            double value,
            const QCPRange & range )  [friend]
```
Multiplies both boundaries of the range by *value*.

17.665.4.3 operator+ [1/2]

```
const QCPRange operator+ (
            const QCPRange & range,
            double value )  [friend]
```
Adds *value* to both boundaries of the range.

17.665.4.4 operator+ [2/2]

```
const QCPRange operator+ (
            double value,
            const QCPRange & range )  [friend]
```
Adds *value* to both boundaries of the range.

17.665.4.5 operator-

```
const QCPRange operator- (
            const QCPRange & range,
            double value )  [friend]
```

Subtracts *value* from both boundaries of the range.

17.665.4.6 operator/

```
const QCPRange operator/ (
            const QCPRange & range,
            double value )  [friend]
```

Divides both boundaries of the range by *value*.

17.665.4.7 operator<<()

```
QDebug operator<< (
            QDebug d,
            const QCPRange & range )  [related]
```

Prints *range* in a human readable format to the qDebug output.

17.665.5 Member Data Documentation

17.665.5.1 maxRange

```
const double QCPRange::maxRange = 1e250  [static]
```

Maximum values (negative and positive) the range will accept in range-changing functions. Larger absolute values would cause errors due to the 11-bit exponent of double precision numbers, corresponding to a maximum magnitude of roughly 1e308.

Warning

Do not use this constant to indicate "arbitrarily large" values in plotting logic (as values that will appear in the plot)! It is intended only as a bound to compare against, e.g. to prevent axis ranges from obtaining overflowing ranges.

See also

validRange, minRange

17.665.5.2 minRange

```
const double QCPRange::minRange = 1e-280  [static]
```

Minimum range size (*upper* - *lower*) the range changing functions will accept. Smaller intervals would cause errors due to the 11-bit exponent of double precision numbers, corresponding to a minimum magnitude of roughly 1e-308.

Warning

Do not use this constant to indicate "arbitrarily small" values in plotting logic (as values that will appear in the plot)! It is intended only as a bound to compare against, e.g. to prevent axis ranges from obtaining underflowing ranges.

- bool **mPenDefined**

17.666.1 Detailed Description

Represents the visual appearance of scatter points.
This class holds information about shape, color and size of scatter points. In plottables like QCPGraph it is used to store how scatter points shall be drawn. For example, QCPGraph::setScatterStyle takes a QCPScatterStyle instance.
A scatter style consists of a shape (setShape), a line color (setPen) and possibly a fill (setBrush), if the shape provides a fillable area. Further, the size of the shape can be controlled with setSize.

17.666.2 Specifying a scatter style

You can set all these configurations either by calling the respective functions on an instance:
Or you can use one of the various constructors that take different parameter combinations, making it easy to specify a scatter style in a single call, like so:

17.666.3 Leaving the color/pen up to the plottable

There are two constructors which leave the pen undefined: QCPScatterStyle() and QCPScatterStyle(ScatterShape shape, double size
If those constructors are used, a call to isPenDefined will return false. It leads to scatter points that inherit the pen from the plottable that uses the scatter style. Thus, if such a scatter style is passed to QCPGraph, the line color of the graph (QCPGraph::setPen) will be used by the scatter points. This makes it very convenient to set up typical scatter settings:
Notice that it wasn't even necessary to explicitly call a QCPScatterStyle constructor. This works because QCPScatterStyle provides a constructor that can transform a ScatterShape directly into a QCPScatterStyle instance (that's the QCPScatterStyle(ScatterShape shape, double size) constructor with a default for *size*). In those cases, C++ allows directly supplying a ScatterShape, where actually a QCPScatterStyle is expected.

17.666.4 Custom shapes and pixmaps

QCPScatterStyle supports drawing custom shapes and arbitrary pixmaps as scatter points.
For custom shapes, you can provide a QPainterPath with the desired shape to the setCustomPath function or call the constructor that takes a painter path. The scatter shape will automatically be set to ssCustom.
For pixmaps, you call setPixmap with the desired QPixmap. Alternatively you can use the constructor that takes a QPixmap. The scatter shape will automatically be set to ssPixmap. Note that setSize does not influence the appearance of the pixmap.

17.666.5 Member Enumeration Documentation

17.666.5.1 ScatterProperty

`enum QCPScatterStyle::ScatterProperty`
Represents the various properties of a scatter style instance. For example, this enum is used to specify which properties of QCPSelectionDecorator::setScatterStyle will be used when highlighting selected data points.
Specific scatter properties can be transferred between QCPScatterStyle instances via setFromOther.

Enumerator

spNone	`0x00` None
spPen	`0x01` The pen property, see setPen
spBrush	`0x02` The brush property, see setBrush
spSize	`0x04` The size property, see setSize
spShape	`0x08` The shape property, see setShape
spAll	`0xFF` All properties

17.666.5.2 ScatterShape

`enum QCPScatterStyle::ScatterShape`

Defines the shape used for scatter points.
On plottables/items that draw scatters, the sizes of these visualizations (with exception of ssDot and ssPixmap) can be controlled with the setSize function. Scatters are drawn with the pen and brush specified with setPen and setBrush.

Enumerator

ssNone	no scatter symbols are drawn (e.g. in QCPGraph, data only represented with lines)
ssDot	\enumimage{ssDot.png} a single pixel (use ssDisc or ssCircle if you want a round shape with a certain radius)
ssCross	\enumimage{ssCross.png} a cross
ssPlus	\enumimage{ssPlus.png} a plus
ssCircle	\enumimage{ssCircle.png} a circle
ssDisc	\enumimage{ssDisc.png} a circle which is filled with the pen's color (not the brush as with ssCircle)
ssSquare	\enumimage{ssSquare.png} a square
ssDiamond	\enumimage{ssDiamond.png} a diamond
ssStar	\enumimage{ssStar.png} a star with eight arms, i.e. a combination of cross and plus
ssTriangle	\enumimage{ssTriangle.png} an equilateral triangle, standing on baseline
ssTriangleInverted	\enumimage{ssTriangleInverted.png} an equilateral triangle, standing on corner
ssCrossSquare	\enumimage{ssCrossSquare.png} a square with a cross inside
ssPlusSquare	\enumimage{ssPlusSquare.png} a square with a plus inside
ssCrossCircle	\enumimage{ssCrossCircle.png} a circle with a cross inside
ssPlusCircle	\enumimage{ssPlusCircle.png} a circle with a plus inside
ssPeace	\enumimage{ssPeace.png} a circle, with one vertical and two downward diagonal lines
ssPixmap	a custom pixmap specified by setPixmap, centered on the data point coordinates
ssCustom	custom painter operations are performed per scatter (As QPainterPath, see setCustomPath)

17.666.6 Constructor & Destructor Documentation

17.666.6.1 QCPScatterStyle() [1/7]

```
QCPScatterStyle::QCPScatterStyle ( )
```

Creates a new QCPScatterStyle instance with size set to 6. No shape, pen or brush is defined.
Since the pen is undefined (isPenDefined returns false), the scatter color will be inherited from the plottable that uses this scatter style.

17.666.6.2 QCPScatterStyle() [2/7]

```
QCPScatterStyle::QCPScatterStyle (
            ScatterShape shape,
            double size = 6 )
```

Creates a new QCPScatterStyle instance with shape set to *shape* and size to *size*. No pen or brush is defined.
Since the pen is undefined (isPenDefined returns false), the scatter color will be inherited from the plottable that uses this scatter style.

17.666.6.3 QCPScatterStyle() [3/7]

```
QCPScatterStyle::QCPScatterStyle (
            ScatterShape shape,
            const QColor & color,
            double size )
```

Creates a new QCPScatterStyle instance with shape set to *shape*, the pen color set to *color*, and size to *size*. No brush is defined, i.e. the scatter point will not be filled.

17.666.6.4 QCPScatterStyle() [4/7]

```
QCPScatterStyle::QCPScatterStyle (
            ScatterShape shape,
            const QColor & color,
            const QColor & fill,
            double size )
```

Creates a new QCPScatterStyle instance with shape set to *shape*, the pen color set to *color*, the brush color to *fill* (with a solid pattern), and size to *size*.

17.666.6.5 QCPScatterStyle() [5/7]

```
QCPScatterStyle::QCPScatterStyle (
            ScatterShape shape,
            const QPen & pen,
            const QBrush & brush,
            double size )
```

Creates a new QCPScatterStyle instance with shape set to *shape*, the pen set to *pen*, the brush to *brush*, and size to *size*.

Warning

> In some cases it might be tempting to directly use a pen style like `Qt::NoPen` as *pen* and a color like `Qt::blue` as *brush*. Notice however, that the corresponding call `QCPScatterStyle(QCPScatterShape::ssCircle, Qt::NoPen, Qt::blue, 5)` doesn't necessarily lead C++ to use this constructor in some cases, but might mistake `Qt::NoPen` for a QColor and use the QCPScatterStyle(ScatterShape shape, const QColor &color, const QColor &fill, double size) constructor instead (which will lead to an unexpected look of the scatter points). To prevent this, be more explicit with the parameter types. For example, use `QBrush(Qt::blue)` instead of just `Qt::blue`, to clearly point out to the compiler that this constructor is wanted.

17.666.6.6 QCPScatterStyle() [6/7]

```
QCPScatterStyle::QCPScatterStyle (
            const QPixmap & pixmap )
```

Creates a new QCPScatterStyle instance which will show the specified *pixmap*. The scatter shape is set to ssPixmap.

17.666.6.7 QCPScatterStyle() [7/7]

```
QCPScatterStyle::QCPScatterStyle (
            const QPainterPath & customPath,
            const QPen & pen,
            const QBrush & brush = Qt::NoBrush,
            double size = 6 )
```

Creates a new QCPScatterStyle instance with a custom shape that is defined via *customPath*. The scatter shape is set to ssCustom.

The custom shape line will be drawn with *pen* and filled with *brush*. The size has a slightly different meaning than for built-in scatter points: The custom path will be drawn scaled by a factor of *size/6.0*. Since the default *size* is 6, the custom path will appear in its original size by default. To for example double the size of the path, set *size* to 12.

17.666.7 Member Function Documentation

17.666.7.1 applyTo()

```
void QCPScatterStyle::applyTo (
```

```
            QCPPainter * painter,
            const QPen & defaultPen ) const
```

Applies the pen and the brush of this scatter style to *painter*. If this scatter style has an undefined pen (isPenDefined), sets the pen of *painter* to *defaultPen* instead.
This function is used by plottables (or any class that wants to draw scatters) just before a number of scatters with this style shall be drawn with the *painter*.

See also

drawShape

17.666.7.2 drawShape() [1/2]

```
void QCPScatterStyle::drawShape (
            QCPPainter * painter,
            const QPointF & pos ) const
```

Draws the scatter shape with *painter* at position *pos*.
This function does not modify the pen or the brush on the painter, as applyTo is meant to be called before scatter points are drawn with drawShape.

See also

applyTo

17.666.7.3 drawShape() [2/2]

```
void QCPScatterStyle::drawShape (
            QCPPainter * painter,
            double x,
            double y ) const
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. Draws the scatter shape with *painter* at position *x* and *y*.

17.666.7.4 isNone()

```
bool QCPScatterStyle::isNone ( ) const  [inline]
```

Returns whether the scatter shape is ssNone.

See also

setShape

17.666.7.5 isPenDefined()

```
bool QCPScatterStyle::isPenDefined ( ) const  [inline]
```

Returns whether a pen has been defined for this scatter style.
The pen is undefined if a constructor is called that does not carry *pen* as parameter. Those are QCPScatterStyle() and QCPScatterStyle(ScatterShape shape, double size). If the pen is undefined, the pen of the respective plottable will be used for drawing scatters.
If a pen was defined for this scatter style instance, and you now wish to undefine the pen, call undefinePen.

See also

setPen

17.666.7.6 setBrush()

```
void QCPScatterStyle::setBrush (
            const QBrush & brush )
```

Sets the brush that will be used to fill scatter points to *brush*. Note that not all scatter shapes have fillable areas. For example, ssPlus does not while ssCircle does.

See also

setPen

17.666.7.7 setCustomPath()

```
void QCPScatterStyle::setCustomPath (
            const QPainterPath & customPath )
```

Sets the custom shape that will be drawn as scatter point to *customPath*.
The scatter shape is automatically set to ssCustom.

17.666.7.8 setFromOther()

```
void QCPScatterStyle::setFromOther (
            const QCPScatterStyle & other,
            ScatterProperties properties )
```

Copies the specified *properties* from the *other* scatter style to this scatter style.

17.666.7.9 setPen()

```
void QCPScatterStyle::setPen (
            const QPen & pen )
```

Sets the pen that will be used to draw scatter points to *pen*.
If the pen was previously undefined (see isPenDefined), the pen is considered defined after a call to this function, even if *pen* is `Qt::NoPen`. If you have defined a pen previously by calling this function and now wish to undefine the pen, call undefinePen.

See also

setBrush

17.666.7.10 setPixmap()

```
void QCPScatterStyle::setPixmap (
            const QPixmap & pixmap )
```

Sets the pixmap that will be drawn as scatter point to *pixmap*.
Note that setSize does not influence the appearance of the pixmap.
The scatter shape is automatically set to ssPixmap.

17.666.7.11 setShape()

```
void QCPScatterStyle::setShape (
            QCPScatterStyle::ScatterShape shape )
```

Sets the shape to *shape*.
Note that the calls setPixmap and setCustomPath automatically set the shape to ssPixmap and ssCustom, respectively.

See also

setSize

17.666.7.12 setSize()

```
void QCPScatterStyle::setSize (
            double size )
```

Sets the size (pixel diameter) of the drawn scatter points to *size*.

See also

setShape

17.666.7.13 undefinePen()

`void QCPScatterStyle::undefinePen ( )`
Sets this scatter style to have an undefined pen (see isPenDefined for what an undefined pen implies).
A call to setPen will define a pen.
The documentation for this class was generated from the following files:

- applications/gui/genesys/qcustomplot.h
- applications/gui/genesys/qcustomplot.cpp

17.667.1 Detailed Description

Controls how a plottable's data selection is drawn.
Each QCPAbstractPlottable instance has one QCPSelectionDecorator (accessible via QCPAbstractPlottable::selectionDecorator) and uses it when drawing selected segments of its data.
The selection decorator controls both pen (setPen) and brush (setBrush), as well as the scatter style (setScatterStyle) if the plottable draws scatters. Since a QCPScatterStyle is itself composed of different properties such as color shape and size, the decorator allows specifying exactly which of those properties shall be used for the selected data point, via setUsedScatterProperties.
A QCPSelectionDecorator subclass instance can be passed to a plottable via QCPAbstractPlottable::setSelectionDecorator, allowing greater customizability of the appearance of selected segments.
Use copyFrom to easily transfer the settings of one decorator to another one. This is especially useful since plottables take ownership of the passed selection decorator, and thus the same decorator instance can not be passed to multiple plottables.
Selection decorators can also themselves perform drawing operations by reimplementing drawDecoration, which is called by the plottable's draw method. The base class QCPSelectionDecorator does not make use of this however. For example, QCPSelectionDecoratorBracket draws brackets around selected data segments.

17.667.2 Constructor & Destructor Documentation

17.667.2.1 QCPSelectionDecorator()

```
QCPSelectionDecorator::QCPSelectionDecorator ( )
```

Creates a new QCPSelectionDecorator instance with default values

17.667.3 Member Function Documentation

17.667.3.1 applyBrush()

```
void QCPSelectionDecorator::applyBrush (
            QCPPainter * painter ) const
```

Sets the brush of *painter* to the brush of this selection decorator.

See also

applyPen, getFinalScatterStyle

17.667.3.2 applyPen()

```
void QCPSelectionDecorator::applyPen (
            QCPPainter * painter ) const
```

Sets the pen of *painter* to the pen of this selection decorator.

See also

applyBrush, getFinalScatterStyle

17.667.3.3 copyFrom()

```
void QCPSelectionDecorator::copyFrom (
            const QCPSelectionDecorator * other )  [virtual]
```

Copies all properties (e.g. color, fill, scatter style) of the *other* selection decorator to this selection decorator.

17.667.3.4 drawDecoration()

```
void QCPSelectionDecorator::drawDecoration (
            QCPPainter * painter,
            QCPDataSelection selection )  [virtual]
```

This method is called by all plottables' draw methods to allow custom selection decorations to be drawn. Use the passed *painter* to perform the drawing operations. *selection* carries the data selection for which the decoration shall be drawn.
The default base class implementation of QCPSelectionDecorator has no special decoration, so this method does nothing.
Reimplemented in QCPSelectionDecoratorBracket.

17.667.3.5 getFinalScatterStyle()

```
QCPScatterStyle QCPSelectionDecorator::getFinalScatterStyle (
            const QCPScatterStyle & unselectedStyle ) const
```

Returns the scatter style that the parent plottable shall use for selected scatter points. The plottable's original (unselected) scatter style must be passed as *unselectedStyle*. Depending on the setting of setUsedScatterProperties, the returned scatter style is a mixture of this selecion decorator's scatter style (setScatterStyle), and *unselectedStyle*.

See also

applyPen, applyBrush, setScatterStyle

17.667.3.6 setBrush()

```
void QCPSelectionDecorator::setBrush (
            const QBrush & brush )
```

Sets the brush that will be used by the parent plottable to draw selected data segments.

17.667.3.7 setPen()

```
void QCPSelectionDecorator::setPen (
            const QPen & pen )
```

Sets the pen that will be used by the parent plottable to draw selected data segments.

17.667.3.8 setScatterStyle()

```
void QCPSelectionDecorator::setScatterStyle (
            const QCPScatterStyle & scatterStyle,
            QCPScatterStyle::ScatterProperties usedProperties = QCPScatterStyle::spPen )
```

Sets the scatter style that will be used by the parent plottable to draw scatters in selected data segments. *usedProperties* specifies which parts of the passed *scatterStyle* will be used by the plottable. The used properties can also be changed via setUsedScatterProperties.

17.667.3.9 setUsedScatterProperties()

```
void QCPSelectionDecorator::setUsedScatterProperties (
            const QCPScatterStyle::ScatterProperties & properties )
```

Use this method to define which properties of the scatter style (set via setScatterStyle) will be used for selected data segments. All properties of the scatter style that are not specified in *properties* will remain as specified in the plottable's original scatter style.

17.668.1 Detailed Description

A selection decorator which draws brackets around each selected data segment.
Additionally to the regular highlighting of selected segments via color, fill and scatter style, this QCPSelectionDecorator subclass draws markers at the begin and end of each selected data segment of the plottable.
The shape of the markers can be controlled with setBracketStyle, setBracketWidth and setBracketHeight. The color/fill can be controlled with setBracketPen and setBracketBrush.
To introduce custom bracket styles, it is only necessary to sublcass QCPSelectionDecoratorBracket and reimplement drawBracket. The rest will be managed by the base class.

17.668.2 Member Enumeration Documentation

17.668.2.1 BracketStyle

`enum QCPSelectionDecoratorBracket::BracketStyle`
Defines which shape is drawn at the boundaries of selected data ranges.
Some of the bracket styles further allow specifying a height and/or width, see setBracketHeight and setBracketWidth.

Enumerator

bsSquareBracket	A square bracket is drawn.
bsHalfEllipse	A half ellipse is drawn. The size of the ellipse is given by the bracket width/height properties.
bsEllipse	An ellipse is drawn. The size of the ellipse is given by the bracket width/height properties.

Enumerator

bsPlus	A plus is drawn.
bsUserStyle	Start custom bracket styles at this index when subclassing and reimplementing drawBracket.

17.668.3 Constructor & Destructor Documentation

17.668.3.1 QCPSelectionDecoratorBracket()

```
QCPSelectionDecoratorBracket::QCPSelectionDecoratorBracket ( )
```

Creates a new QCPSelectionDecoratorBracket instance with default values.

17.668.4 Member Function Documentation

17.668.4.1 drawBracket()

```
void QCPSelectionDecoratorBracket::drawBracket (
            QCPPainter * painter,
            int direction ) const  [virtual]
```

Draws the bracket shape with *painter*. The parameter *direction* is either -1 or 1 and indicates whether the bracket shall point to the left or the right (i.e. is a closing or opening bracket, respectively).
The passed *painter* already contains all transformations that are necessary to position and rotate the bracket appropriately. Painting operations can be performed as if drawing upright brackets on flat data with horizontal key axis, with (0, 0) being the center of the bracket.
If you wish to sublcass QCPSelectionDecoratorBracket in order to provide custom bracket shapes (see QCPSelectionDecoratorBracket::bsUserStyle), this is the method you should reimplement.

17.668.4.2 drawDecoration()

```
void QCPSelectionDecoratorBracket::drawDecoration (
            QCPPainter * painter,
            QCPDataSelection selection )  [virtual]
```

Draws the bracket decoration on the data points at the begin and end of each selected data segment given in *seletion*.
It uses the method drawBracket to actually draw the shapes.
\seebaseclassmethod
Reimplemented from QCPSelectionDecorator.

17.668.4.3 setBracketBrush()

```
void QCPSelectionDecoratorBracket::setBracketBrush (
            const QBrush & brush )
```

Sets the brush that will be used to draw the brackets at the beginning and end of each selected data segment.

17.668.4.4 setBracketHeight()

```
void QCPSelectionDecoratorBracket::setBracketHeight (
            int height )
```

Sets the height of the drawn bracket. The height dimension is always perpendicular to the key axis of the data, or the tangent direction of the current data slope, if setTangentToData is enabled.

17.668.4.5 setBracketPen()

```
void QCPSelectionDecoratorBracket::setBracketPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the brackets at the beginning and end of each selected data segment.

17.668.4.6 setBracketStyle()

```
void QCPSelectionDecoratorBracket::setBracketStyle (
            QCPSelectionDecoratorBracket::BracketStyle style )
```

Sets the shape that the bracket/marker will have.

See also

setBracketWidth, setBracketHeight

17.668.4.7 setBracketWidth()

```
void QCPSelectionDecoratorBracket::setBracketWidth (
            int width )
```

Sets the width of the drawn bracket. The width dimension is always parallel to the key axis of the data, or the tangent direction of the current data slope, if setTangentToData is enabled.

17.668.4.8 setTangentAverage()

```
void QCPSelectionDecoratorBracket::setTangentAverage (
            int pointCount )
```

Controls over how many data points the slope shall be averaged, when brackets shall be aligned with the data (if setTangentToData is true).
From the position of the bracket, *pointCount* points towards the selected data range will be taken into account. The smallest value of *pointCount* is 1, which is effectively equivalent to disabling setTangentToData.

17.668.4.9 setTangentToData()

```
void QCPSelectionDecoratorBracket::setTangentToData (
            bool enabled )
```

Sets whether the brackets will be rotated such that they align with the slope of the data at the position that they appear in.
For noisy data, it might be more visually appealing to average the slope over multiple data points. This can be configured via setTangentAverage.

17.669.1 Detailed Description

Provides rect/rubber-band data selection and range zoom interaction.
QCPSelectionRect is used by QCustomPlot when the QCustomPlot::setSelectionRectMode is not QCP::srmNone. When the user drags the mouse across the plot, the current selection rect instance (QCustomPlot::setSelectionRect) is forwarded these events and makes sure an according rect shape is drawn. At the begin, during, and after completion of the interaction, it emits the corresponding signals started, changed, canceled, and accepted.
The QCustomPlot instance connects own slots to the current selection rect instance, in order to react to an accepted selection rect interaction accordingly.
isActive can be used to check whether the selection rect is currently active. An ongoing selection interaction can be cancelled programmatically via calling cancel at any time.
The appearance of the selection rect can be controlled via setPen and setBrush.
If you wish to provide custom behaviour, e.g. a different visual representation of the selection rect (QCPSelectionRect::draw), you can subclass QCPSelectionRect and pass an instance of your subclass to QCustomPlot::setSelectionRect.

17.669.2 Constructor & Destructor Documentation

17.669.2.1 QCPSelectionRect()

```
QCPSelectionRect::QCPSelectionRect (
            QCustomPlot * parentPlot )  [explicit]
```

Creates a new QCPSelectionRect instance. To make QCustomPlot use the selection rect instance, pass it to QCustomPlot::setSelectionRect. *parentPlot* should be set to the same QCustomPlot widget.

17.669.3 Member Function Documentation

17.669.3.1 accepted

```
void QCPSelectionRect::accepted (
            const QRect & rect,
            QMouseEvent * event )  [signal]
```

This signal is emitted when the selection interaction was completed by the user releasing the mouse button.

Note that *rect* may have a negative width or height, if the selection is being dragged to the upper or left side of the selection rect origin.

17.669.3.2 applyDefaultAntialiasingHint()

```
void QCPSelectionRect::applyDefaultAntialiasingHint (
            QCPPainter * painter ) const  [protected], [virtual]
```

Implements QCPLayerable.

17.669.3.3 cancel()

```
void QCPSelectionRect::cancel ( )
```

If there is currently a selection interaction going on (isActive), the interaction is canceled. The selection rect will emit the canceled signal.

17.669.3.4 canceled

```
void QCPSelectionRect::canceled (
            const QRect & rect,
            QInputEvent * event )  [signal]
```

This signal is emitted when the selection interaction was cancelled. Note that *event* is `nullptr` if the selection interaction was cancelled programmatically, by a call to cancel.
The user may cancel the selection interaction by pressing the escape key. In this case, *event* holds the respective input event.
Note that *rect* may have a negative width or height, if the selection is being dragged to the upper or left side of the selection rect origin.

17.669.3.5 changed

```
void QCPSelectionRect::changed (
            const QRect & rect,
            QMouseEvent * event )  [signal]
```

This signal is emitted while the selection rect interaction is ongoing and the *rect* has changed its size due to the user moving the mouse.
Note that *rect* may have a negative width or height, if the selection is being dragged to the upper or left side of the selection rect origin.

17.669.3.6 draw()

```
void QCPSelectionRect::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPLayerable.

17.669.3.7 isActive()

```
bool QCPSelectionRect::isActive ( ) const  [inline]
```

Returns true if there is currently a selection going on, i.e. the user has started dragging a selection rect, but hasn't released the mouse button yet.

See also

cancel

17.669.3.8 range()

```
QCPRange QCPSelectionRect::range (
            const QCPAxis * axis ) const
```

A convenience function which returns the coordinate range of the provided *axis*, that this selection rect currently encompasses.

17.669.3.9 setBrush()

```
void QCPSelectionRect::setBrush (
            const QBrush & brush )
```

Sets the brush that will be used to fill the selection rect. By default the selection rect is not filled, i.e. *brush* is `Qt::NoBrush`.

See also

setPen

17.669.3.10 setPen()

```
void QCPSelectionRect::setPen (
            const QPen & pen )
```

Sets the pen that will be used to draw the selection rect outline.

See also

setBrush

17.669.3.11 started

```
void QCPSelectionRect::started (
            QMouseEvent * event )  [signal]
```

This signal is emitted when a selection rect interaction was initiated, i.e. the user just started dragging the selection rect with the mouse.

17.670.1 Detailed Description

A plottable representing a single statistical box in a plot.
To plot data, assign it with the setData or addData functions. Alternatively, you can also access and modify the data via the data method, which returns a pointer to the internal QCPStatisticalBoxDataContainer.
Additionally each data point can itself have a list of outliers, drawn as scatter points at the key coordinate of the respective statistical box data point. They can either be set by using the respective addData method or accessing the individual data points through data, and setting the `QVector<double> outliers` of the data points directly.

17.670.2 Changing the appearance

The appearance of each data point box, ranging from the lower to the upper quartile, is controlled via setPen and setBrush. You may change the width of the boxes with setWidth in plot coordinates.
Each data point's visual representation also consists of two whiskers. Whiskers are the lines which reach from the upper quartile to the maximum, and from the lower quartile to the minimum. The appearance of the whiskers can be modified with: setWhiskerPen, setWhiskerBarPen, setWhiskerWidth. The whisker width is the width of the bar perpendicular to the whisker at the top (for maximum) and bottom (for minimum). If the whisker pen is changed, make sure to set the `capStyle` to `Qt::FlatCap`. Otherwise the backbone line might exceed the whisker bars by a few pixels due to the pen cap being not perfectly flat.
The median indicator line inside the box has its own pen, setMedianPen.
The outlier data points are drawn as normal scatter points. Their look can be controlled with setOutlierStyle

17.670.3 Usage

Like all data representing objects in QCustomPlot, the QCPStatisticalBox is a plottable (QCPAbstractPlottable). So the plottable-interface of QCustomPlot applies (QCustomPlot::plottable, QCustomPlot::removePlottable, etc.)
Usually, you first create an instance:
which registers it with the QCustomPlot instance of the passed axes. Note that this QCustomPlot instance takes ownership of the plottable, so do not delete it manually but use QCustomPlot::removePlottable() instead. The newly created plottable can be modified, e.g.:

17.670.4 Constructor & Destructor Documentation

17.670.4.1 QCPStatisticalBox()

```
QCPStatisticalBox::QCPStatisticalBox (
            QCPAxis * keyAxis,
            QCPAxis * valueAxis )  [explicit]
```

Constructs a statistical box which uses *keyAxis* as its key axis ("x") and *valueAxis* as its value axis ("y"). *keyAxis* and *valueAxis* must reside in the same QCustomPlot instance and not have the same orientation. If either of these restrictions is violated, a corresponding message is printed to the debug output (qDebug), the construction is not aborted, though.

The created QCPStatisticalBox is automatically registered with the QCustomPlot instance inferred from *keyAxis*. This QCustomPlot instance takes ownership of the QCPStatisticalBox, so do not delete it manually but use QCustomPlot::removePlottable() instead.

17.670.5 Member Function Documentation

17.670.5.1 addData() [1/2]

```
void QCPStatisticalBox::addData (
            const QVector< double > & keys,
            const QVector< double > & minimum,
            const QVector< double > & lowerQuartile,
            const QVector< double > & median,
            const QVector< double > & upperQuartile,
            const QVector< double > & maximum,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Adds the provided points in *keys*, *minimum*, *lowerQuartile*, *median*, *upperQuartile* and *maximum* to the current data. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.

If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.

Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.670.5.2 addData() [2/2]

```
void QCPStatisticalBox::addData (
            double key,
            double minimum,
            double lowerQuartile,
            double median,
            double upperQuartile,
            double maximum,
            const QVector< double > & outliers = QVector<double>() )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

Adds the provided data point as *key*, *minimum*, *lowerQuartile*, *median*, *upperQuartile* and *maximum* to the current data.

Alternatively, you can also access and modify the data directly via the data method, which returns a pointer to the internal data container.

17.670.5.3 data()

```
QSharedPointer< QCPStatisticalBoxDataContainer > QCPStatisticalBox::data ( ) const  [inline]
```

Returns a shared pointer to the internal data storage of type QCPStatisticalBoxDataContainer. You may use it to directly manipulate the data, which may be more convenient and faster than using the regular setData or addData methods.

17.670.5.4 draw()

```
void QCPStatisticalBox::draw (
            QCPPainter * painter )  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.670.5.5 drawLegendIcon()

```
void QCPStatisticalBox::drawLegendIcon (
            QCPPainter * painter,
            const QRectF & rect ) const  [protected], [virtual]
```

Implements QCPAbstractPlottable.

17.670.5.6 drawStatisticalBox()

```
void QCPStatisticalBox::drawStatisticalBox (
            QCPPainter * painter,
            QCPStatisticalBoxDataContainer::const_iterator it,
            const QCPScatterStyle & outlierStyle ) const  [protected], [virtual]
```

Draws the graphical representation of a single statistical box with the data given by the iterator *it* with the provided *painter*.
If the statistical box has a set of outlier data points, they are drawn with *outlierStyle*.

See also

getQuartileBox, getWhiskerBackboneLines, getWhiskerBarLines

17.670.5.7 getKeyRange()

```
QCPRange QCPStatisticalBox::getKeyRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth ) const  [virtual]
```

Returns the coordinate range that all data in this plottable span in the key axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSignDomain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getValueRange

Implements QCPAbstractPlottable.

17.670.5.8 getValueRange()

```
QCPRange QCPStatisticalBox::getValueRange (
            bool & foundRange,
            QCP::SignDomain inSignDomain = QCP::sdBoth,
            const QCPRange & inKeyRange = QCPRange() ) const  [virtual]
```

Returns the coordinate range that the data points in the specified key range (*inKeyRange*) span in the value axis dimension. For logarithmic plots, one can set *inSignDomain* to either QCP::sdNegative or QCP::sdPositive in order to restrict the returned range to that sign domain. E.g. when only negative range is wanted, set *inSignDomain* to QCP::sdNegative and all positive points will be ignored for range calculation. For no restriction, just set *inSign↩ Domain* to QCP::sdBoth (default). *foundRange* is an output parameter that indicates whether a range could be found or not. If this is false, you shouldn't use the returned range (e.g. no points in data).

If *inKeyRange* has both lower and upper bound set to zero (is equal to `QCPRange()`), all data points are considered, without any restriction on the keys.
Note that *foundRange* is not the same as QCPRange::validRange, since the range returned by this function may have size zero (e.g. when there is only one data point). In this case *foundRange* would return true, but the returned range is not a valid range in terms of QCPRange::validRange.

See also

rescaleAxes, getKeyRange

Implements QCPAbstractPlottable.

17.670.5.9 selectTest()

```
double QCPStatisticalBox::selectTest (
            const QPointF & pos,
            bool onlySelectable,
            QVariant * details = nullptr ) const  [virtual]
```

Implements a selectTest specific to this plottable's point geometry.
If *details* is not 0, it will be set to a QCPDataSelection, describing the closest data point to *pos*.
\seebaseclassmethod QCPAbstractPlottable::selectTest
Reimplemented from QCPAbstractPlottable1D< QCPStatisticalBoxData >.

17.670.5.10 selectTestRect()

```
QCPDataSelection QCPStatisticalBox::selectTestRect (
            const QRectF & rect,
            bool onlySelectable ) const  [virtual]
```

Returns a data selection containing all the data points of this plottable which are contained (or hit by) *rect*. This is used mainly in the selection rect interaction for data selection (data selection mechanism).
If *onlySelectable* is true, an empty QCPDataSelection is returned if this plottable is not selectable (i.e. if QCPAbstractPlottable::setSelectable is QCP::stNone).

Note

rect must be a normalized rect (positive or zero width and height). This is especially important when using the rect of QCPSelectionRect::accepted, which is not necessarily normalized. Use `QRect::normalized()` when passing a rect which might not be normalized.

Reimplemented from QCPAbstractPlottable1D< QCPStatisticalBoxData >.

17.670.5.11 setData() [1/2]

```
void QCPStatisticalBox::setData (
            const QVector< double > & keys,
            const QVector< double > & minimum,
            const QVector< double > & lowerQuartile,
            const QVector< double > & median,
            const QVector< double > & upperQuartile,
            const QVector< double > & maximum,
            bool alreadySorted = false )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data with the provided points in *keys*, *minimum*, *lowerQuartile*, *median*, *upperQuartile* and *maximum*. The provided vectors should have equal length. Else, the number of added points will be the size of the smallest vector.
If you can guarantee that the passed data points are sorted by *keys* in ascending order, you can set *alreadySorted* to true, to improve performance by saving a sorting run.

See also

addData

17.670.5.12 setData() [2/2]

```
void QCPStatisticalBox::setData (
            QSharedPointer< QCPStatisticalBoxDataContainer > data )
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.
Replaces the current data container with the provided *data* container.
Since a QSharedPointer is used, multiple QCPStatisticalBoxes may share the same data container safely. Modifying the data in the container will then affect all statistical boxes that share the container. Sharing can be achieved by simply exchanging the data containers wrapped in shared pointers:
If you do not wish to share containers, but create a copy from an existing container, rather use the QCPDataContainer<DataType>::set method on the statistical box data container directly:

See also

addData

17.670.5.13 setMedianPen()

```
void QCPStatisticalBox::setMedianPen (
            const QPen & pen )
```

Sets the pen used for drawing the median indicator line inside the statistical boxes.

17.670.5.14 setOutlierStyle()

```
void QCPStatisticalBox::setOutlierStyle (
            const QCPScatterStyle & style )
```

Sets the appearance of the outlier data points.
Outliers can be specified with the method addData(double key, double minimum, double lowerQuartile, double median, double upperQ

17.670.5.15 setWhiskerAntialiased()

```
void QCPStatisticalBox::setWhiskerAntialiased (
            bool enabled )
```

Sets whether the statistical boxes whiskers are drawn with antialiasing or not.
Note that antialiasing settings may be overridden by QCustomPlot::setAntialiasedElements and QCustomPlot::setNotAntialiasedEleme

17.670.5.16 setWhiskerBarPen()

```
void QCPStatisticalBox::setWhiskerBarPen (
            const QPen & pen )
```

Sets the pen used for drawing the whisker bars. Those are the lines parallel to the key axis at each end of the whisker backbone.
Whiskers are the lines which reach from the upper quartile to the maximum, and from the lower quartile to the minimum.

See also

setWhiskerPen

17.670.5.17 setWhiskerPen()

```
void QCPStatisticalBox::setWhiskerPen (
            const QPen & pen )
```

Sets the pen used for drawing the whisker backbone.
Whiskers are the lines which reach from the upper quartile to the maximum, and from the lower quartile to the minimum.
Make sure to set the `capStyle` of the passed *pen* to `Qt::FlatCap`. Otherwise the backbone line might exceed the whisker bars by a few pixels due to the pen cap being not perfectly flat.

See also

setWhiskerBarPen

17.670.5.18 setWhiskerWidth()

```
void QCPStatisticalBox::setWhiskerWidth (
            double width )
```

Sets the width of the whiskers in key coordinates.
Whiskers are the lines which reach from the upper quartile to the maximum, and from the lower quartile to the minimum.

See also

setWidth

17.670.5.19 setWidth()

```
void QCPStatisticalBox::setWidth (
            double width )
```

Sets the width of the boxes in key coordinates.

See also

setWhiskerWidth

- double **median**
- double **upperQuartile**
- double **maximum**
- QVector< double > **outliers**

17.671.1 Detailed Description

Holds the data of one single data point for QCPStatisticalBox.
The stored data is:

- *key:* coordinate on the key axis of this data point (this is the *mainKey* and the *sortKey*)
- *minimum:* the position of the lower whisker, typically the minimum measurement of the sample that's not considered an outlier.
- *lowerQuartile:* the lower end of the box. The lower and the upper quartiles are the two statistical quartiles around the median of the sample, they should contain 50% of the sample data.
- *median:* the value of the median mark inside the quartile box. The median separates the sample data in half (50% of the sample data is below/above the median). (This is the *mainValue*)
- *upperQuartile:* the upper end of the box. The lower and the upper quartiles are the two statistical quartiles around the median of the sample, they should contain 50% of the sample data.
- *maximum:* the position of the upper whisker, typically the maximum measurement of the sample that's not considered an outlier.
- *outliers:* a QVector of outlier values that will be drawn as scatter points at the *key* coordinate of this data point (see QCPStatisticalBox::setOutlierStyle)

The container for storing multiple data points is QCPStatisticalBoxDataContainer. It is a typedef for QCPDataContainer with QCPStatisticalBoxData as the DataType template parameter. See the documentation there for an explanation regarding the data type's generic methods.

QCPStatisticalBoxDataContainer

17.671.2 Constructor & Destructor Documentation

17.671.2.1 QCPStatisticalBoxData() [1/2]

```
QCPStatisticalBoxData::QCPStatisticalBoxData ( )
```

Constructs a data point with key and all values set to zero.

17.671.2.2 QCPStatisticalBoxData() [2/2]

```
QCPStatisticalBoxData::QCPStatisticalBoxData (
            double key,
            double minimum,
            double lowerQuartile,
            double median,
            double upperQuartile,
            double maximum,
            const QVector< double > & outliers = QVector<double>() )
```

Constructs a data point with the specified *key*, *minimum*, *lowerQuartile*, *median*, *upperQuartile*, *maximum* and optionally a number of *outliers*.

17.671.3 Member Function Documentation

17.671.3.1 fromSortKey()

```
static QCPStatisticalBoxData QCPStatisticalBoxData::fromSortKey (
            double sortKey )  [inline], [static]
```

Returns a data point with the specified *sortKey*. All other members are set to zero.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.671.3.2 mainKey()

```
double QCPStatisticalBoxData::mainKey ( ) const  [inline]
```

Returns the *key* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.671.3.3 mainValue()

```
double QCPStatisticalBoxData::mainValue ( ) const  [inline]
```

Returns the *median* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.671.3.4 sortKey()

```
double QCPStatisticalBoxData::sortKey ( ) const  [inline]
```

Returns the *key* member of this data point.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.671.3.5 sortKeyIsMainKey()

```
static static bool QCPStatisticalBoxData::sortKeyIsMainKey ( )  [inline], [static]
```

Since the member *key* is both the data point key coordinate and the data ordering parameter, this method returns true.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.671.3.6 valueRange()

```
QCPRange QCPStatisticalBoxData::valueRange ( ) const  [inline]
```

Returns a QCPRange spanning from the *minimum* to the *maximum* member of this statistical box data point, possibly further expanded by outliers.
For a general explanation of what this method is good for in the context of the data container, see the documentation of QCPDataContainer.

17.672.1 Detailed Description

A layout element displaying a text.
The text may be specified with setText, the formatting can be controlled with setFont, setTextColor, and setTextFlags.
A text element can be added as follows:

17.672.2 Constructor & Destructor Documentation

17.672.2.1 QCPTextElement() [1/5]

```
QCPTextElement::QCPTextElement (
            QCustomPlot * parentPlot )  [explicit]
```
