18.73.1 Detailed Description

Composition-root partition of MainWindow implementation.
This file contains central MainWindow construction, initialization, and wiring logic, including creation of extracted controllers/services and baseline UI setup. It does not define a new class; it is a physical partition of the same MainWindow implementation used as a compatibility façade in the incremental refactoring.

18.75.1 Detailed Description

Controller-delegation partition of MainWindow implementation.
This file groups menu/toolbar/widget slot wrappers that delegate behavior to extracted controllers (for example lifecycle, simulation command, edit, scene tool, and dialog utility controllers). It does not define a new class; it is a thematic partition of MainWindow.

18.76 applications/gui/genesys/mainwindow_modelrepresentations.cpp File Reference

Model representation/persistence wrapper partition of MainWindow implementation.

Include dependency graph for mainwindow_modelrepresentations.cpp:

18.76.1 Detailed Description

Model representation/persistence wrapper partition of MainWindow implementation.
This file groups MainWindow wrappers related to textual synchronization, Graphviz and C++ exports, graphical persistence/serialization, and graphical model reconstruction through extracted services/controllers. It does not define a new class; it is a thematic partition of MainWindow.

18.77 applications/gui/genesys/mainwindow_scene.cpp File Reference

Scene callback and scene synchronization partition of MainWindow implementation.

```
#include "mainwindow.h"

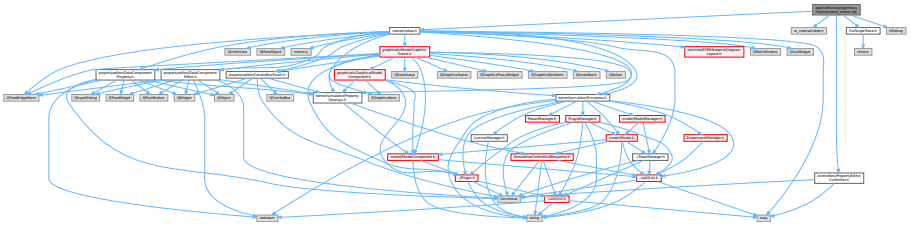
```

Include dependency graph for mainwindow_scene.cpp:



18.77.1 Detailed Description

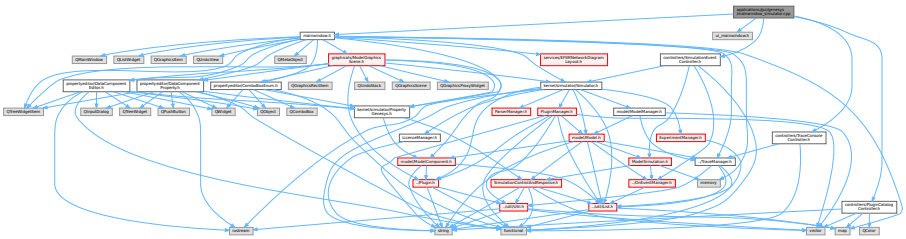
Scene callback and scene synchronization partition of MainWindow implementation.
This file concentrates scene-related callbacks, selection/focus/zoom bridging, and wrappers that synchronize scene state with UI elements such as actions and the property editor controller. It does not define a new class; it is a thematic partition of MainWindow.

18.78 applications/gui/genesys/mainwindow_simulator.cpp File Reference

Simulator trace/event wrapper partition of MainWindow implementation.

```
#include "mainwindow.h"
#include "ui_mainwindow.h"
#include "controllers/TraceConsoleController.h"
#include "controllers/SimulationEventController.h"
#include "controllers/PluginCatalogController.h"
```

Include dependency graph for mainwindow_simulator.cpp:



18.78.1 Detailed Description

Simulator trace/event wrapper partition of MainWindow implementation.

This file centralizes MainWindow compatibility wrappers for simulator traces and simulation event callbacks, delegating rendering and reactions to TraceConsoleController and SimulationEventController (plus plugin-catalog related delegation where applicable). It does not define a new class; it is a thematic partition of MainWindow.

00050 /* class A needs to have dll-interface to be used by clients of class B */)
00051
00052 namespace testing {
00053
00054     // A class for indicating whether an assertion was successful.  When
00055     // the assertion wasn't successful, the AssertionResult object
00056     // remembers a non-empty message that describes how it failed.
00057     //
00058     // To create an instance of this class, use one of the factory functions
00059     // (AssertionSuccess() and AssertionFailure()).
00060     //
```

```
00061     // This class is useful for two purposes:
00062     //   1. Defining predicate functions to be used with Boolean test assertions
00063     //      EXPECT_TRUE/EXPECT_FALSE and their ASSERT_ counterparts
00064     //   2. Defining predicate-format functions to be
00065     //      used with predicate assertions (ASSERT_PRED_FORMAT*, etc).
00066     //
00067     // For example, if you define IsEven predicate:
00068     //
00069     //   testing::AssertionResult IsEven(int n) {
00070     //     if ((n % 2) == 0)
00071     //       return testing::AssertionSuccess();
00072     //     else
00073     //       return testing::AssertionFailure() « n « " is odd";
00074     //   }
00075     //
00076     // Then the failed expectation EXPECT_TRUE(IsEven(Fib(5)))
00077     // will print the message
00078     //
00079     //   Value of: IsEven(Fib(5))
00080     //     Actual: false (5 is odd)
00081     //   Expected: true
00082     //
00083     // instead of a more opaque
00084     //
00085     //   Value of: IsEven(Fib(5))
00086     //     Actual: false
00087     //   Expected: true
00088     //
00089     // in case IsEven is a simple Boolean predicate.
00090     //
00091     // If you expect your predicate to be reused and want to support informative
00092     // messages in EXPECT_FALSE and ASSERT_FALSE (negative assertions show up
00093     // about half as often as positive ones in our tests), supply messages for
00094     // both success and failure cases:
00095     //
00096     //   testing::AssertionResult IsEven(int n) {
00097     //     if ((n % 2) == 0)
00098     //       return testing::AssertionSuccess() « n « " is even";
00099     //     else
00100     //       return testing::AssertionFailure() « n « " is odd";
00101     //   }
00102     //
00103     // Then a statement EXPECT_FALSE(IsEven(Fib(6))) will print
00104     //
00105     //   Value of: IsEven(Fib(6))
00106     //     Actual: true (8 is even)
00107     //   Expected: false
00108     //
00109     // NB: Predicates that support negative Boolean assertions have reduced
00110     // performance in positive ones so be careful not to use them in tests
00111     // that have lots (tens of thousands) of positive Boolean assertions.
00112     //
00113     // To use this class with EXPECT_PRED_FORMAT assertions such as:
00114     //
00115     //   // Verifies that Foo() returns an even number.
00116     //   EXPECT_PRED_FORMAT1(IsEven, Foo());
00117     //
00118     // you need to define:
00119     //
00120     //   testing::AssertionResult IsEven(const char* expr, int n) {
00121     //     if ((n % 2) == 0)
00122     //       return testing::AssertionSuccess();
00123     //     else
00124     //       return testing::AssertionFailure()
00125     //         « "Expected: " « expr « " is even\n  Actual: it's " « n;
00126     //   }
00127     //
00128     // If Foo() returns 5, you will see the following message:
00129     //
00130     //   Expected: Foo() is even
00131     //     Actual: it's 5
00132     //

```
00066
00067     // The following macros are useful for writing death tests.
00068
00069     // Here's what happens when an ASSERT_DEATH* or EXPECT_DEATH* is
00070     // executed:
00071     //
00072     //   1. It generates a warning if there is more than one active
00073     //   thread.  This is because it's safe to fork() or clone() only
00074     //   when there is a single thread.
00075     //
00076     //   2. The parent process clone()s a sub-process and runs the death
00077     //   test in it; the sub-process exits with code 0 at the end of the
00078     //   death test, if it hasn't exited already.
00079     //
00080     //   3. The parent process waits for the sub-process to terminate.
00081     //
00082     //   4. The parent process checks the exit code and error message of
00083     //   the sub-process.
00084     //
00085     // Examples:
00086     //
00087     //   ASSERT_DEATH(server.SendMessage(56, "Hello"), "Invalid port number");
00088     //   for (int i = 0; i < 5; i++) {
00089     //     EXPECT_DEATH(server.ProcessRequest(i),
00090     //                  "Invalid request .* in ProcessRequest()")
00091     //                  « "Failed to die on request " « i;
00092     //   }
00093     //
00094     //   ASSERT_EXIT(server.ExitNow(), ::testing::ExitedWithCode(0), "Exiting");
00095     //
00096     //   bool KilledBySIGHUP(int exit_code) {
00097     //     return WIFSIGNALED(exit_code) && WTERMSIG(exit_code) == SIGHUP;
00098     //   }
00099     //
00100     //   ASSERT_EXIT(client.HangUpServer(), KilledBySIGHUP, "Hanging up!");
00101     //
00102     // The final parameter to each of these macros is a matcher applied to any data
00103     // the sub-process wrote to stderr.  For compatibility with existing tests, a
00104     // bare string is interpreted as a regular expression matcher.
00105     //
00106     // On the regular expressions used in death tests:
00107     //
00108     //   On POSIX-compliant systems (*nix), we use the <regex.h> library,
00109     //   which uses the POSIX extended regex syntax.
00110     //
00111     //   On other platforms (e.g. Windows or Mac), we only support a simple regex
00112     //   syntax implemented as part of Google Test.  This limited
00113     //   implementation should be enough most of the time when writing
00114     //   death tests; though it lacks many features you can find in PCRE
00115     //   or POSIX extended regex syntax.  For example, we don't support
00116     //   union ("x|y"), grouping ("(xy)"), brackets ("[xy]"), and
00117     //   repetition count ("x{5,7}"), among others.
00118     //
00119     //   Below is the syntax that we do support.  We chose it to be a
00120     //   subset of both PCRE and POSIX extended regex, so it's easy to
00121     //   learn wherever you come from.  In the following: 'A' denotes a
00122     //   literal character, period (.), or a single \\ escape sequence;
00123     //   'x' and 'y' denote regular expressions; 'm' and 'n' are for
00124     //   natural numbers.
00125     //
00126     //     c     matches any literal character c
00127     //     \\d   matches any decimal digit
00128     //     \\D   matches any character that's not a decimal digit
00129     //     \\f   matches \f
00130     //     \\n   matches \n
00131     //     \\r   matches \r
00132     //     \\s   matches any ASCII whitespace, including \n
00133     //     \\S   matches any character that's not a whitespace
00134     //     \\t   matches \t
00135     //     \\v   matches \v
00136     //     \\w   matches any letter, _, or decimal digit
00137     //     \\W   matches any character that \\w doesn't match
00138     //     \\c   matches any literal character c, which must be a punctuation
00139     //     .     matches any single character except \n
00140     //     A?    matches 0 or 1 occurrences of A
00141     //     A*    matches 0 or many occurrences of A
00142     //     A+    matches 1 or many occurrences of A
00143     //     ^     matches the beginning of a string (not that of each line)
00144     //     $     matches the end of a string (not that of each line)
00145     //     xy    matches x followed by y
00146     //
00147     //   If you accidentally use PCRE or POSIX extended regex features
00148     //   not implemented by us, you will get a run-time failure.  In that
00149     //   case, please try to rewrite your regular expression within the
00150     //   above syntax.
00151     //
00152     //   This implementation is *not* meant to be as highly tuned or robust
```

```
00153     //   as a compiled regex library, but should perform well enough for a
00154     //   death test, which already incurs significant overhead by launching
00155     //   a child process.
00156     //
00157     // Known caveats:
00158     //
00159     //   A "threadsafe" style death test obtains the path to the test
00160     //   program from argv[0] and re-executes it in the sub-process.  For
00161     //   simplicity, the current implementation doesn't search the PATH
00162     //   when launching the sub-process.  This means that the user must
00163     //   invoke the test program via a path that contains at least one
00164     //   path separator (e.g. path/to/foo_test and
00165     //   /absolute/path/to/bar_test are fine, but foo_test is not).  This
00166     //   is rarely a problem as people usually don't put the test binary
00167     //   directory in PATH.
00168     //
00169
00170     // Asserts that a given `statement` causes the program to exit, with an

00280
00281     // This macro is used for implementing macros such as
00282     // EXPECT_DEATH_IF_SUPPORTED and ASSERT_DEATH_IF_SUPPORTED on systems where
00283     // death tests are not supported. Those macros must compile on such systems
00284     // if and only if EXPECT_DEATH and ASSERT_DEATH compile with the same parameters
00285     // on systems that support death tests. This allows one to write such a macro on
00286     // a system that does not support death tests and be sure that it will compile
00287     // on a death-test supporting system. It is exposed publicly so that systems
00288     // that have death-tests with stricter requirements than GTEST_HAS_DEATH_TEST
00289     // can write their own equivalent of EXPECT_DEATH_IF_SUPPORTED and
00290     // ASSERT_DEATH_IF_SUPPORTED.
00291     //
00292     // Parameters:
00293     //   statement -  A statement that a macro such as EXPECT_DEATH would test
00294     //                for program termination. This macro has to make sure this
00295     //                statement is compiled but not executed, to ensure that
00296     //                EXPECT_DEATH_IF_SUPPORTED compiles with a certain
00297     //                parameter if and only if EXPECT_DEATH compiles with it.
00298     //   regex     -  A regex that a macro such as EXPECT_DEATH would use to test
00299     //                the output of statement.  This parameter has to be
00300     //                compiled but not evaluated by this macro, to ensure that
00301     //                this macro only accepts expressions that a macro such as
00302     //                EXPECT_DEATH would accept.
00303     //   terminator - Must be an empty statement for EXPECT_DEATH_IF_SUPPORTED
00304     //                and a return statement for ASSERT_DEATH_IF_SUPPORTED.
00305     //                This ensures that ASSERT_DEATH_IF_SUPPORTED will not
00306     //                compile inside functions where ASSERT_DEATH doesn't
00307     //                compile.
00308     //
00309     //  The branch that has an always false condition is used to ensure that
00310     //  statement and regex are compiled (and thus syntactically correct) but
00311     //  never executed. The unreachable code macro protects the terminator
00312     //  statement from generating an 'unreachable code' warning in case
00313     //  statement unconditionally returns or throws. The Message constructor at
00314     //  the end allows the syntax of streaming additional messages into the
00315     //  macro, for compilational compatibility with EXPECT_DEATH/ASSERT_DEATH.

00040 // Value-parameterized tests allow you to test your code with different
00041 // parameters without writing multiple copies of the same test.
00042 //
00043 // Here is how you use value-parameterized tests:
00044
00045 #if 0
00046
00047 // To write value-parameterized tests, first you should define a fixture
00048 // class. It is usually derived from testing::TestWithParam<T> (see below for
00049 // another inheritance scheme that's sometimes useful in more complicated
00050 // class hierarchies), where the type of your parameter values.
00051 // TestWithParam<T> is itself derived from testing::Test. T can be any
00052 // copyable type. If it's a raw pointer, you are responsible for managing the
00053 // lifespan of the pointed values.
00054
00055 class FooTest : public ::testing::TestWithParam<const char*> {
00056   // You can implement all the usual class fixture members here.
00057 };
00058
00059 // Then, use the TEST_P macro to define as many parameterized tests
00060 // for this fixture as you want. The _P suffix is for "parameterized"
00061 // or "pattern", whichever you prefer to think.
00062
00063 TEST_P(FooTest, DoesBlah) {
00064   // Inside a test, access the test parameter with the GetParam() method
00065   // of the TestWithParam<T> class:
00066   EXPECT_TRUE(foo.Blah(GetParam()));
00067   ...

```

```
00075 // case with any set of parameters you want. Google Test defines a number
00076 // of functions for generating test parameters. They return what we call
00077 // (surprise!) parameter generators. Here is a summary of them, which
00078 // are all in the testing namespace:
00079 //
00080 //
00081 //  Range(begin, end [, step]) - Yields values {begin, begin+step,
00082 //                               begin+step+step, ...}. The values do not
00083 //                               include end. step defaults to 1.
00084 //  Values(v1, v2, ..., vN)    - Yields values {v1, v2, ..., vN}.
00085 //  ValuesIn(container)        - Yields values from a C-style array, an STL
00086 //  ValuesIn(begin,end)          container, or an iterator range [begin, end).
00087 //  Bool()                     - Yields sequence {false, true}.
00088 //  Combine(g1, g2, ..., gN)   - Yields all combinations (the Cartesian product
00089 //                               for the math savvy) of the values generated
00090 //                               by the N generators.
00091 //
00092 // For more details, see comments at the definitions of these functions below
00093 // in this file.
00094 //
00095 // The following statement will instantiate tests from the FooTest test suite
00096 // each with parameter values "meeny", "miny", and "moe".
00097
00098 INSTANTIATE_TEST_SUITE_P(InstantiationName,
00099                          FooTest,
00100                          Values("meeny", "miny", "moe"));
00101
00102 // To distinguish different instances of the pattern, (yes, you
00103 // can instantiate it more than once) the first argument to the
00104 // INSTANTIATE_TEST_SUITE_P macro is a prefix that will be added to the
00105 // actual test suite name. Remember to pick unique prefixes for different
00106 // instantiations. The tests from the instantiation above will have
00107 // these names:
00108 //
00109 //    * InstantiationName/FooTest.DoesBlah/0 for "meeny"
00110 //    * InstantiationName/FooTest.DoesBlah/1 for "miny"
00111 //    * InstantiationName/FooTest.DoesBlah/2 for "moe"
00112 //    * InstantiationName/FooTest.HasBlahBlah/0 for "meeny"
00113 //    * InstantiationName/FooTest.HasBlahBlah/1 for "miny"
00114 //    * InstantiationName/FooTest.HasBlahBlah/2 for "moe"
00115 //
00116 // You can use these names in --gtest_filter.
00117 //
00118 // This statement will instantiate all tests from FooTest again, each
00119 // with parameter values "cat" and "dog":
00120
00121 const char* pets[] = {"cat", "dog"};
00122 INSTANTIATE_TEST_SUITE_P(AnotherInstantiationName, FooTest, ValuesIn(pets));
00123
00124 // The tests from the instantiation above will have these names:
00125 //
00126 //    * AnotherInstantiationName/FooTest.DoesBlah/0 for "cat"
00127 //    * AnotherInstantiationName/FooTest.DoesBlah/1 for "dog"
00128 //    * AnotherInstantiationName/FooTest.HasBlahBlah/0 for "cat"
00129 //    * AnotherInstantiationName/FooTest.HasBlahBlah/1 for "dog"
00130 //
00131 // Please note that INSTANTIATE_TEST_SUITE_P will instantiate all tests
00132 // in the given test suite, whether their definitions come before or
00133 // AFTER the INSTANTIATE_TEST_SUITE_P statement.
00134 //
00135 // Please also note that generator expressions (including parameters to the
00136 // generators) are evaluated in InitGoogleTest(), after main() has started.
00137 // This allows the user on one hand, to adjust generator parameters in order
00138 // to dynamically determine a set of tests to run and on the other hand,
00139 // give the user a chance to inspect the generated tests with Google Test
00140 // reflection API before RUN_ALL_TESTS() is executed.
00141 //
00142 // You can see samples/sample7_unittest.cc and samples/sample8_unittest.cc
00143 // for more examples.
00144 //
00145 // In the future, we plan to publish the API for defining new parameter
00146 // generators. But for now this interface remains part of the internal
00147 // implementation and is subject to change.
00148 //
00149 //
00150 // A parameterized test fixture must be derived from testing::Test and from
00151 // testing::WithParamInterface<T>, where T is the type of the parameter
00152 // values. Inheriting from TestWithParam<T> satisfies that requirement because
00153 // TestWithParam<T> inherits from both Test and WithParamInterface. In more
00154 // complicated hierarchies, however, it is occasionally useful to inherit
00155 // separately from Test and WithParamInterface. For example:
00156
00157 class BaseTest : public ::testing::Test {
00158   // You can inherit all the usual members for a non-parameterized test
00159   // fixture here.
00160 };
00161
```

```
00162 class DerivedTest : public BaseTest, public ::testing::WithParamInterface<int> {
00163   // The usual test fixture members go here too.
00164 };
00165
00166 TEST_F(BaseTest, HasFoo) {
00167   // This is an ordinary non-parameterized test.
00168 }
00169
00170 TEST_P(DerivedTest, DoesBlah) {
00171   // GetParam works just the same here as if you inherit from TestWithParam.
00172   EXPECT_TRUE(foo.Blah(GetParam()));
00173 }
00174
00175 #endif  // 0
00176
00177 #include <iterator>
00178 #include <utility>
00179
00180 #include "gtest/internal/gtest-internal.h"
00181 #include "gtest/internal/gtest-param-util.h"
00182 #include "gtest/internal/gtest-port.h"
00183
00184 namespace testing {
00185
00186 // Functions producing parameter generators.
00187 //
00188 // Google Test uses these generators to produce parameters for value-
00189 // parameterized tests. When a parameterized test suite is instantiated
00190 // with a particular generator, Google Test creates and runs tests
00191 // for each element in the sequence produced by the generator.
00192 //
00193 // In the following sample, tests from test suite FooTest are instantiated
00194 // each three times with parameter values 3, 5, and 8:
00195 //
00196 // class FooTest : public TestWithParam<int> { ... };
00197 //
00198 // TEST_P(FooTest, TestThis) {
00199 // }
00200 // TEST_P(FooTest, TestThat) {
00201 // }
00202 // INSTANTIATE_TEST_SUITE_P(TestSequence, FooTest, Values(3, 5, 8));
00203 //
00204
00205 // Range() returns generators providing sequences of values in a range.
00206 //
00207 // Synopsis:
00208 // Range(start, end)
00209 //   - returns a generator producing a sequence of values {start, start+1,
00210 //     start+2, ..., }.
00211 // Range(start, end, step)
00212 //   - returns a generator producing a sequence of values {start, start+step,
00213 //     start+step+step, ..., }.
00214 // Notes:
00215 //   * The generated sequences never include end. For example, Range(1, 5)
00216 //     returns a generator producing a sequence {1, 2, 3, 4}. Range(1, 9, 2)
00217 //     returns a generator producing {1, 3, 5, 7}.
00218 //   * start and end must have the same type. That type may be any integral or
00219 //     floating-point type or a user defined type satisfying these conditions:
00220 //     * It must be assignable (have operator=() defined).
00221 //     * It must have operator+() (operator+(int-compatible type) for
00222 //       two-operand version).
00223 //     * It must have operator<() defined.
00224 //     Elements in the resulting sequences will also have that type.
00225 //   * Condition start < end must be satisfied in order for resulting sequences
00226 //     to contain any elements.
00227 //
00228 template <typename T, typename IncrementT>
00229 internal::ParamGenerator<T> Range(T start, T end, IncrementT step) {

00238
00239 // ValuesIn() function allows generation of tests with parameters coming from
00240 // a container.
00241 //
00242 // Synopsis:
00243 // ValuesIn(const T (&array)[N])
00244 //   - returns a generator producing sequences with elements from
00245 //     a C-style array.
00246 // ValuesIn(const Container& container)
00247 //   - returns a generator producing sequences with elements from
00248 //     an STL-style container.
```

```
00249 // ValuesIn(Iterator begin, Iterator end)
00250 //   - returns a generator producing sequences with elements from
00251 //     a range [begin, end) defined by a pair of STL-style iterators. These
00252 //     iterators can also be plain C pointers.
00253 //
00254 // Please note that ValuesIn copies the values from the containers
00255 // passed in and keeps them to generate tests in RUN_ALL_TESTS().
00256 //
00257 // Examples:
00258 //
00259 // This instantiates tests from test suite StringTest
00260 // each with C-string values of "foo", "bar", and "baz":
00261 //
00262 // const char* strings[] = {"foo", "bar", "baz"};
00263 // INSTANTIATE_TEST_SUITE_P(StringSequence, StringTest, ValuesIn(strings));
00264 //
00265 // This instantiates tests from test suite StlStringTest
00266 // each with STL strings with values "a" and "b":
00267 //
00268 // ::std::vector< ::std::string> GetParameterStrings() {
00269 //   ::std::vector< ::std::string> v;
00270 //   v.push_back("a");
00271 //   v.push_back("b");
00272 //   return v;
00273 // }
00274 //
00275 // INSTANTIATE_TEST_SUITE_P(CharSequence,
00276 //                          StlStringTest,
00277 //                          ValuesIn(GetParameterStrings()));
00278 //
00279 //
00280 // This will also instantiate tests from CharTest
00281 // each with parameter values 'a' and 'b':
00282 //
00283 // ::std::list<char> GetParameterChars() {
00284 //   ::std::list<char> list;
00285 //   list.push_back('a');
00286 //   list.push_back('b');
00287 //   return list;
00288 // }
00289 // ::std::list<char> l = GetParameterChars();
00290 // INSTANTIATE_TEST_SUITE_P(CharSequence2,
00291 //                          CharTest,
00292 //                          ValuesIn(l.begin(), l.end()));
00293 //
00294 template <typename ForwardIterator>

00337 }
00338
00339 // Bool() allows generating tests with parameters in a set of (false, true).
00340 //
00341 // Synopsis:
00342 // Bool()
00343 //   - returns a generator producing sequences with elements {false, true}.
00344 //
00345 // It is useful when testing code that depends on Boolean flags. Combinations
00346 // of multiple flags can be tested when several Bool()'s are combined using
00347 // Combine() function.
00348 //
00349 // In the following example all tests in the test suite FlagDependentTest
00350 // will be instantiated twice with parameters false and true.
00351 //
00352 // class FlagDependentTest : public testing::TestWithParam<bool> {
00353 //   virtual void SetUp() {
00354 //     external_flag = GetParam();
00355 //   }
00356 // }
00357 // INSTANTIATE_TEST_SUITE_P(BoolSequence, FlagDependentTest, Bool());
00358 //
00359 inline internal::ParamGenerator<bool> Bool() { return Values(false, true); }
00360
00361 // Combine() allows the user to combine two or more sequences to produce
00362 // values of a Cartesian product of those sequences' elements.
00363 //
00364 // Synopsis:
00365 // Combine(gen1, gen2, ..., genN)
00366 //   - returns a generator producing sequences with elements coming from
00367 //     the Cartesian product of elements from the sequences generated by
00368 //     gen1, gen2, ..., genN. The sequence elements will have a type of
00369 //     std::tuple<T1, T2, ..., TN> where T1, T2, ..., TN are the types
00370 //     of elements from sequences produces by gen1, gen2, ..., genN.
00371 //
00372 // Example:
00373 //
00374 // This will instantiate tests in test suite AnimalTest each one with
00375 // the parameter values tuple("cat", BLACK), tuple("cat", WHITE),
00376 // tuple("dog", BLACK), and tuple("dog", WHITE):
00377 //
00378 // enum Color { BLACK, GRAY, WHITE };
00379 // class AnimalTest
00380 //     : public testing::TestWithParam<std::tuple<const char*, Color> > {...};
00381 //
00382 // TEST_P(AnimalTest, AnimalLooksNice) {...}
00383 //
00384 // INSTANTIATE_TEST_SUITE_P(AnimalVariations, AnimalTest,
00385 //                          Combine(Values("cat", "dog"),
00386 //                                  Values(BLACK, WHITE)));
00387 //
00388 // This will instantiate tests in FlagDependentTest with all variations of two
00389 // Boolean flags:
00390 //
00391 // class FlagDependentTest
00392 //     : public testing::TestWithParam<std::tuple<bool, bool> > {
00393 //   virtual void SetUp() {
00394 //     // Assigns external_flag_1 and external_flag_2 values from the tuple.
00395 //     std::tie(external_flag_1, external_flag_2) = GetParam();
00396 //   }
00397 // };
00398 //
00399 // TEST_P(FlagDependentTest, TestFeature1) {
00400 //   // Test your code using external_flag_1 and external_flag_2 here.
00401 // }
00402 // INSTANTIATE_TEST_SUITE_P(TwoBoolSequence, FlagDependentTest,

00030 // Google Test - The Google C++ Testing and Mocking Framework
00031 //
00032 // This file implements a universal value printer that can print a
00033 // value of any type T:
00034 //
00035 //   void ::testing::internal::UniversalPrinter<T>::Print(value, ostream_ptr);
00036 //
00037 // A user can teach this function how to print a class type T by
00038 // defining either operator<<() or PrintTo() in the namespace that
00039 // defines T.  More specifically, the FIRST defined function in the
00040 // following list will be used (assuming T is defined in namespace
00041 // foo):
00042 //
00043 //   1. foo::PrintTo(const T&, ostream*)
00044 //   2. operator<<(ostream&, const T&) defined in either foo or the
00045 //      global namespace.
00046 //
00047 // However if T is an STL-style container then it is printed element-wise
00048 // unless foo::PrintTo(const T&, ostream*) is defined. Note that
00049 // operator<<() is ignored for container types.
00050 //
00051 // If none of the above is defined, it will print the debug string of
00052 // the value if it is a protocol buffer, or print the raw bytes in the
00053 // value otherwise.
00054 //
00055 // To aid debugging: when T is a reference type, the address of the
00056 // value is also printed; when T is a (const) char pointer, both the
00057 // pointer value and the NUL-terminated string it points to are
00058 // printed.
00059 //
00060 // We also provide some convenient wrappers:
00061 //
00062 //   // Prints a value to a string.  For a (const or not) char
00063 //   // pointer, the NUL-terminated string (but not the pointer) is
00064 //   // printed.
00065 //   std::string ::testing::PrintToString(const T& value);
00066 //
00067 //   // Prints a value tersely: for a reference type, the referenced
00068 //   // value (but not the address) is printed; for a (const or not) char
00069 //   // pointer, the NUL-terminated string (but not the pointer) is
00070 //   // printed.
00071 //   void ::testing::internal::UniversalTersePrint(const T& value, ostream*);
00072 //
00073 //   // Prints value using the type inferred by the compiler.  The difference
00074 //   // from UniversalTersePrint() is that this function prints both the
00075 //   // pointer and the NUL-terminated string for a (const or not) char pointer.
00076 //   void ::testing::internal::UniversalPrint(const T& value, ostream*);
00077 //
00078 //   // Prints the fields of a tuple tersely to a string vector, one
00079 //   // element for each field. Tuple support must be enabled in
00080 //   // gtest-port.h.
00081 //   std::vector<string> UniversalTersePrintTupleFieldsToStrings(
```

```
00082 //       const Tuple& value);
00083 //
00084 // Known limitation:
00085 //
00086 // The print primitives print the elements of an STL-style container
00087 // using the compiler-inferred type of *iter where iter is a
00088 // const_iterator of the container.  When const_iterator is an input
00089 // iterator but not a forward iterator, this inferred type may not
00090 // match value_type, and the print output may be incorrect.  In
00091 // practice, this is rarely a problem as for most containers
00092 // const_iterator is a forward iterator.  We'll fix this if there's an
00093 // actual need for it.  Note that this fix cannot rely on value_type
00094 // being defined as many user-defined container types don't have
00095 // value_type.

00037 // This header implements typed tests and type-parameterized tests.
00038
00039 // Typed (aka type-driven) tests repeat the same test for types in a
00040 // list.  You must know which types you want to test with when writing
00041 // typed tests. Here's how you do it:
00042
00043 #if 0
00044
```

```
00045 // First, define a fixture class template.  It should be parameterized
00046 // by a type.  Remember to derive it from testing::Test.
00047
00048 template <typename T>
00049 class FooTest : public testing::Test {
00050 public:
00051     ...
00052     typedef std::list<T> List;
00053     static T shared_;
00054     T value_;
00055 };
00056
00057 // Next, associate a list of types with the test suite, which will be
00058 // repeated for each type in the list.  The typedef is necessary for
00059 // the macro to parse correctly.
00060 typedef testing::Types<char, int, unsigned int> MyTypes;
00061 TYPED_TEST_SUITE(FooTest, MyTypes);
00062
00063 // If the type list contains only one type, you can write that type
00064 // directly without Types<...>:
00065 //   TYPED_TEST_SUITE(FooTest, int);
00066
00067 // Then, use TYPED_TEST() instead of TEST_F() to define as many typed
00068 // tests for this test suite as you want.
00069
00070 TYPED_TEST(FooTest, DoesBlah) {
00071     // Inside a test, refer to the special name TypeParam to get the type
00072     // parameter.  Since we are inside a derived class template, C++ requires
00073     // us to visit the members of FooTest via 'this'.
00074     TypeParam n = this->value_;
00075
00076     // To visit static members of the fixture, add the TestFixture::
00077     // prefix.
00078     n += TestFixture::shared_;
00079
00080     // To refer to typedefs in the fixture, add the "typename
00081     // TestFixture::" prefix.
00082     typename TestFixture::List values;
00083     values.push_back(n);
00084     ...
00085 }
00086
00087 TYPED_TEST(FooTest, HasPropertyA) {
00088     ...
00089 }
00090
00091 // TYPED_TEST_SUITE takes an optional third argument which allows to specify a
00092 // class that generates custom test name suffixes based on the type. This should
00093 // be a class which has a static template function GetName(int index) returning
00094 // a string for each type. The provided integer index equals the index of the
00095 // type in the provided type list. In many cases the index can be ignored.
00096 //
00097 // For example:
00098 //   class MyTypeNames {
00099 //    public:
00100 //     template <typename T>
00101 //     static std::string GetName(int) {
00102 //       if (std::is_same<T, char>()) return "char";
00103 //       if (std::is_same<T, int>()) return "int";
00104 //       if (std::is_same<T, unsigned int>()) return "unsignedInt";
00105 //     }
00106 //   };
00107 //   TYPED_TEST_SUITE(FooTest, MyTypes, MyTypeNames);
00108
00109 #endif  // 0
00110
00111 // Type-parameterized tests are abstract test patterns parameterized
00112 // by a type.  Compared with typed tests, type-parameterized tests
00113 // allow you to define the test pattern without knowing what the type
00114 // parameters are.  The defined pattern can be instantiated with
00115 // different types any number of times, in any number of translation
00116 // units.
00117 //
00118 // If you are designing an interface or concept, you can define a
00119 // suite of type-parameterized tests to verify properties that any
00120 // valid implementation of the interface/concept should have.  Then,
00121 // each implementation can easily instantiate the test suite to verify
00122 // that it conforms to the requirements, without having to write
00123 // similar tests repeatedly.  Here's an example:
00124
00125 #if 0
00126
00127 // First, define a fixture class template.  It should be parameterized
00128 // by a type.  Remember to derive it from testing::Test.
00129
00130 template <typename T>
00131 class FooTest : public testing::Test {
```

```
00132     ...
00133 };
00134
00135 // Next, declare that you will define a type-parameterized test suite
00136 // (the _P suffix is for "parameterized" or "pattern", whichever you
00137 // prefer):
00138 TYPED_TEST_SUITE_P(FooTest);
00139
00140 // Then, use TYPED_TEST_P() to define as many type-parameterized tests
00141 // for this type-parameterized test suite as you want.
00142
00143 TYPED_TEST_P(FooTest, DoesBlah) {
00144     // Inside a test, refer to TypeParam to get the type parameter.
00145     TypeParam n = 0;
00146     ...
00147 }
00148
00149 TYPED_TEST_P(FooTest, HasPropertyA) {
00150     ...
00151 }
00152
00153 // Now the tricky part: you need to register all test patterns before
00154 // you can instantiate them.  The first argument of the macro is the
00155 // test suite name; the rest are the names of the tests in this test
00156 // case.
00157 REGISTER_TYPED_TEST_SUITE_P(FooTest,
00158         DoesBlah, HasPropertyA);
00159
00160 // Finally, you are free to instantiate the pattern with the types you
00161 // want.  If you put the above code in a header file, you can #include
00162 // it in multiple C++ source files and instantiate it multiple times.
00163 //
00164 // To distinguish different instances of the pattern, the first
00165 // argument to the INSTANTIATE_* macro is a prefix that will be added
00166 // to the actual test suite name.  Remember to pick unique prefixes for
00167 // different instances.
00168 typedef testing::Types<char, int, unsigned int> MyTypes;

02422     // Dynamically registers a test with the framework.
02423     //
02424     // This is an advanced API only to be used when the `TEST` macros are
02425     // insufficient. The macros should be preferred when possible, as they avoid
02426     // most of the complexity of calling this function.
02427     //
02428     // The `factory` argument is a factory callable (move-constructible) object or
02429     // function pointer that creates a new instance of the Test object. It
02430     // handles ownership to the caller. The signature of the callable is
02431     // `Fixture*()`, where `Fixture` is the test fixture class for the test. All
02432     // tests registered with the same `test_suite_name` must return the same
02433     // fixture type. This is checked at runtime.
02434     //
02435     // The framework will infer the fixture class from the factory and will call
02436     // the `SetUpTestSuite` and `TearDownTestSuite` for it.
02437     //
02438     // Must be called before `RUN_ALL_TESTS()` is invoked, otherwise behavior is
02439     // undefined.
02440     //
02441     // Use case example:
02442     //
02443     // class MyFixture : public ::testing::Test {
02444     //  public:
02445     //   // All of these optional, just like in regular macro usage.
02446     //   static void SetUpTestSuite() { ... }
02447     //   static void TearDownTestSuite() { ... }
02448     //   void SetUp() override { ... }

00047
00048 // Environment-describing macros
00049 // -----------------------------
00050 //
00051 // Google Test can be used in many different environments.  Macros in
00052 // this section tell Google Test what kind of environment it is being
00053 // used in, such that Google Test can provide environment-specific
00054 // features and implementations.
00055 //
00056 // Google Test tries to automatically detect the properties of its
00057 // environment, so users usually don't need to worry about these
00058 // macros.  However, the automatic detection is not perfect.
00059 // Sometimes it's necessary for a user to define some of the following
00060 // macros in the build script to override Google Test's decisions.
00061 //
00062 // If the user doesn't define a macro in the list, Google Test will
00063 // provide a default definition.  After this header is #included, all
00064 // macros in this list will be defined to either 1 or 0.
00065 //
00066 // Notes to maintainers:
00067 //   - Each macro here is a user-tweakable knob; do not grow the list
00068 //     lightly.
00069 //   - Use #if to key off these macros.  Don't use #ifdef or "#if
00070 //     defined(...)", which will not work as these macros are ALWAYS
00071 //     defined.
00072 //
00073 //   GTEST_HAS_CLONE          - Define it to 1/0 to indicate that clone(2)
00074 //                              is/isn't available.
00075 //   GTEST_HAS_EXCEPTIONS     - Define it to 1/0 to indicate that exceptions
00076 //                              are enabled.
00077 //   GTEST_HAS_POSIX_RE       - Define it to 1/0 to indicate that POSIX regular
00078 //                              expressions are/aren't available.
00079 //   GTEST_HAS_PTHREAD        - Define it to 1/0 to indicate that <pthread.h>
00080 //                              is/isn't available.
00081 //   GTEST_HAS_RTTI           - Define it to 1/0 to indicate that RTTI is/isn't
00082 //                              enabled.
00083 //   GTEST_HAS_STD_WSTRING    - Define it to 1/0 to indicate that

00141 //   GTEST_OS_ZOS      - z/OS
00142 //
00143 // Among the platforms, Cygwin, Linux, Mac OS X, and Windows have the
00144 // most stable support.  Since core members of the Google Test project
00145 // don't have access to other platforms, support for them may be less
00146 // stable.  If you notice any problems on your platform, please notify
00147 // googletestframework@googlegroups.com (patches for fixing them are
00148 // even more welcome!).
00149 //
00150 // It is possible that none of the GTEST_OS_* macros are defined.
00151
00152 // Feature-indicating macros
00153 // -------------------------
00154 //
00155 // Macros indicating which Google Test features are available (a macro
00156 // is defined to 1 if the corresponding feature is supported;
00157 // otherwise UNDEFINED -- it's never defined to 0.).  Google Test
00158 // defines these macros automatically.  Code outside Google Test MUST
00159 // NOT define them.
00160 //
00161 // These macros are public so that portable tests can be written.
00162 // Such tests typically surround code using a feature with an #if
00163 // which controls that code.  For example:
00164 //
00165 // #if GTEST_HAS_DEATH_TEST
00166 //   EXPECT_DEATH(DoSomethingDeadly());
00167 // #endif
00168 //
00169 //   GTEST_HAS_DEATH_TEST   - death tests
00170 //   GTEST_HAS_TYPED_TEST   - typed tests
00171 //   GTEST_HAS_TYPED_TEST_P - type-parameterized tests
00172 //   GTEST_IS_THREADSAFE    - Google Test is thread-safe.
00173 //   GTEST_USES_RE2         - the RE2 regular expression library is used
00174 //   GTEST_USES_POSIX_RE    - enhanced POSIX regex is used. Do not confuse with
00175 //                            GTEST_HAS_POSIX_RE (see above) which users can
00176 //                            define themselves.
00177 //   GTEST_USES_SIMPLE_RE   - our own simple regex is used;
00178 //                            the above RE\b(s) are mutually exclusive.
00179
00180 // Misc public macros
00181 // ------------------
00182 //
00183 //   GTEST_FLAG(flag_name)  - references the variable corresponding to
00184 //                            the given Google Test flag.
00185
00186 // Internal utilities
00187 // ------------------
00188 //
00189 // The following macros and utilities are for Google Test's INTERNAL
00190 // use only.  Code outside Google Test MUST NOT USE THEM DIRECTLY.
00191 //
00192 // Macros for basic C++ coding:
00193 //   GTEST_AMBIGUOUS_ELSE_BLOCKER_ - for disabling a gcc warning.
00194 //   GTEST_ATTRIBUTE_UNUSED_  - declares that a class' instances or a
00195 //                              variable don't have to be used.
00196 //   GTEST_MUST_USE_RESULT_   - declares that a function's result must be used.
00197 //   GTEST_INTENTIONAL_CONST_COND_PUSH_ - start code section where MSVC C4127 is
00198 //                                       suppressed (constant conditional).
00199 //   GTEST_INTENTIONAL_CONST_COND_POP_  - finish code section where MSVC C4127
00200 //                                       is suppressed.
00201 //   GTEST_INTERNAL_HAS_ANY - for enabling UniversalPrinter<std::any> or
00202 //                            UniversalPrinter<absl::any> specializations.
00203 //   GTEST_INTERNAL_HAS_OPTIONAL - for enabling UniversalPrinter<std::optional>
00204 //   or
00205 //                                 UniversalPrinter<absl::optional>
00206 //                                 specializations.
00207 //   GTEST_INTERNAL_HAS_STRING_VIEW - for enabling Matcher<std::string_view> or
00208 //                                    Matcher<absl::string_view>
00209 //                                    specializations.
00210 //   GTEST_INTERNAL_HAS_VARIANT - for enabling UniversalPrinter<std::variant> or
```

```
00211 //                               UniversalPrinter<absl::variant>
00212 //                               specializations.
00213 //
00214 // Synchronization:
00215 //   Mutex, MutexLock, ThreadLocal, GetThreadCount()
00216 //                           - synchronization primitives.
00217 //
00218 // Regular expressions:
00219 //   RE             - a simple regular expression class using
00220 //                      1) the RE2 syntax on all platforms when built with RE2
00221 //                         and Abseil as dependencies
00222 //                      2) the POSIX Extended Regular Expression syntax on
00223 //                         UNIX-like platforms,
00224 //                      3) A reduced regular exception syntax on other platforms,
00225 //                         including Windows.
00226 // Logging:
00227 //   GTEST_LOG_()   - logs messages at the specified severity level.
00228 //   LogToStderr()  - directs all log messages to stderr.
00229 //   FlushInfoLog() - flushes informational log messages.
00230 //
00231 // Stdout and stderr capturing:
00232 //   CaptureStdout()     - starts capturing stdout.
00233 //   GetCapturedStdout() - stops capturing stdout and returns the captured
00234 //                         string.
00235 //   CaptureStderr()     - starts capturing stderr.
00236 //   GetCapturedStderr() - stops capturing stderr and returns the captured
00237 //                         string.
00238 //
00239 // Integer types:
00240 //   TypeWithSize   - maps an integer to a int type.
00241 //   TimeInMillis   - integers of known sizes.
00242 //   BiggestInt     - the biggest signed integer type.
00243 //
00244 // Command-line utilities:
00245 //   GetInjectableArgvs() - returns the command line as a vector of strings.
00246 //
00247 // Environment variable utilities:
00248 //   GetEnv()             - gets the value of an environment variable.
00249 //   BoolFromGTestEnv()   - parses a bool environment variable.
00250 //   Int32FromGTestEnv()  - parses an int32_t environment variable.
00251 //   StringFromGTestEnv() - parses a string environment variable.
00252 //
00253 // Deprecation warnings:
00254 //   GTEST_INTERNAL_DEPRECATED(message) - attribute marking a function as
00255 //                                        deprecated; calling a marked function

```
01081         // INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE.
01082         //
01083         // Use ImplicitCast_ as a safe version of static_cast for upcasting in
01084         // the type hierarchy (e.g. casting a Foo* to a SuperclassOfFoo* or a
01085         // const Foo*).  When you use ImplicitCast_, the compiler checks that
01086         // the cast is safe.  Such explicit ImplicitCast_s are necessary in
01087         // surprisingly many situations where C++ demands an exact type match
01088         // instead of an argument type convertible to a target type.
01089         //
01090         // The syntax for using ImplicitCast_ is the same as for static_cast:
01091         //
01092         //   ImplicitCast_<ToType>(expr)
01093         //
01094         // ImplicitCast_ would have been part of the C++ standard library,
01095         // but the proposal was submitted too late.  It will probably make
01096         // its way into the language in the future.
01097         //
01098         // This relatively ugly name is intentional. It prevents clashes with
01099         // similar functions users may have (e.g., implicit_cast). The internal
01100         // namespace alone is not enough because the function can be found by ADL.
01101
01102         template <typename To>
01103         inline To ImplicitCast_(To x) {
01104             return x;
01105         }
01106
01107         // When you upcast (that is, cast a pointer from type Foo to type
01108         // SuperclassOfFoo), it's fine to use ImplicitCast_<>, since upcasts
01109         // always succeed.  When you downcast (that is, cast a pointer from
01110         // type Foo to type SubclassOfFoo), static_cast<> isn't safe, because
01111         // how do you know the pointer is really of type SubclassOfFoo?  It
01112         // could be a bare Foo, or of type DifferentSubclassOfFoo.  Thus,
01113         // when you downcast, you should use this macro.  In debug mode, we
01114         // use dynamic_cast<> to double-check the downcast is legal (we die
01115         // if it's not).  In normal mode, we do the efficient static_cast<>
01116         // instead.  Thus, it's important to test in debug mode to make sure
01117         // the cast is legal!
01118         //    This is the only place in the code we should use dynamic_cast<>.
01119         // In particular, you SHOULDN'T be using dynamic_cast<> in order to
01120         // do RTTI (eg code like this:
01121         //    if (dynamic_cast<Subclass1>(foo)) HandleASubclass1Object(foo);
01122         //    if (dynamic_cast<Subclass2>(foo)) HandleASubclass2Object(foo);
01123         // You should design the code some other way not to need this.
01124         //
01125         // This relatively ugly name is intentional. It prevents clashes with
01126         // similar functions users may have (e.g., down_cast). The internal

00686         // WindowsDeathTest implements death tests on Windows. Due to the
00687         // specifics of starting new processes on Windows, death tests there are
00688         // always threadsafe, and Google Test considers the
00689         // --gtest_death_test_style=fast setting to be equivalent to
00690         // --gtest_death_test_style=threadsafe there.
00691         //
00692         // A few implementation notes:  Like the Linux version, the Windows
00693         // implementation uses pipes for child-to-parent communication. But due to
00694         // the specifics of pipes on Windows, some extra steps are required:
00695         //
00696         // 1. The parent creates a communication pipe and stores handles to both
00697         //    ends of it.
00698         // 2. The parent starts the child and provides it with the information
00699         //    necessary to acquire the handle to the write end of the pipe.
00700         // 3. The child acquires the write end of the pipe and signals the parent
00701         //    using a Windows event.
00702         // 4. Now the parent can release the write end of the pipe on its side. If
00703         //    this is done before step 3, the object's reference count goes down to
00704         //    0 and it is destroyed, preventing the child from acquiring it. The
00705         //    parent now has to release it, or read operations on the read end of
00706         //    the pipe will not return when the child terminates.
00707         // 5. The parent reads child's output through the pipe (outcome code and
00708         //    any possible error messages) from the pipe, and its stderr and then
00709         //    determines whether to fail the test.
